PUBLICATION OF THE COMMITTEE OF THE FUTURE 2/2026

---

## **COMMITTEE FOR THE FUTURE: ANTICIPATING SOCIETAL DEVELOPMENT**

The Committee for the Future is one of the 17 standing committees of the Parliament of Finland.

Committee for the Future provides information for decision-making by organising expert hearings and by commissioning research projects and reports.

Committee for the Future

- Acts as Parliament's reporting committee for the Government Report on the Future
- Explores future trends, scenarios and related issues
- Monitors sustainable development policies
- Follows futures studies and its methodological development
- Pays special attention to technological development and anticipates its impact on the society

Committee for the Future also organises public hearings and maintains a publication series.

# Arvoisa lukija,

käsissäsi on raportti, jonka on tarkoitus olla muutakin kuin katsaus uusiin teknologioihin. Sen tehtävänä on auttaa pysähtymään sen äärelle, miten nopeasti ympäröivä maailma muuttuu ja miksi tuota muutosta on syytä tarkastella vakavasti jo ennen kuin sen seuraukset näkyvät kaikkialla arjessamme. Juuri tästä syystä radikaalien teknologioiden ennakointi (RTI) on ollut eduskunnan tulevaisuusvaliokunnalle tärkeää työtä jo pitkään. Olemme halunneet ymmärtää ajoissa, mitkä teknologiat voivat muuttaa yhteiskunnan toimintaa syvästi, missä järjestyksessä muutokset voivat edetä ja millaisiin kysymyksiin päätöksenteon pitäisi osata vastata ennen kuin on liian myöhäistä.

Tässä raportissa jatkuu työ, jota on tehty RTI-menetelmällä jo vuodesta 2013 lähtien. Perusajatus on ollut alusta asti kunnianhimoinen: emme tyydy luettelemaan kiinnostavia teknologioita, vaan pyrimme rakentamaan niistä kokonaiskuvan, joka on hyödyllinen lainsäätäjille, tutkijoille, yrityksille, opettajille, viranomaisille ja kansalaisille. Tulevaisuutta ei voi hallita, jos sitä ei ensin pyri hahmottamaan. Siksi tässäkin raportissa on lähdetty liikkeelle samasta kunnianhimoisesta tavoitteesta kuin aiemmin: tunnistetaan sata sellaista eri kypsyysvaiheissa olevaa radikaalia teknologiaa, joiden vaikutukset voivat ulottua laajasti yhteiskunnan eri toimintoihin, ja tarkastellaan niitä 20 arvonluontiverkoston kautta.

Tällä kertaa työssä on kuitenkin mukana myös jotakin olennaisesti uutta. Generatiivinen tekoäly on tullut mukaan tutkimusprosessiin tavalla, joka olisi vielä muutama vuosi sitten tuntunut epärealistiselta. On ollut tärkeää nähdä käytännössä, miten tekoäly voi auttaa laajojen aineistojen läpikäynnissä, teknologiakokonaisuuksien jäsentämisessä, lähdepohjaisessa kuvaustyössä ja vaikutusten ennakoinnissa.

Samalla on ollut aivan yhtä tärkeää nähdä sen rajat. Tekoäly ei korvaa harkintaa, vastuuta eikä tutkimuksellista arviointia. Siksi pidämme tämän raportin ehkä tärkeimpänä metodologisena opetuksena sitä, että hyvä ennakointi voi vahvistua tekoälyn avulla, mutta sitä ei voi ulkoistaa tekoälylle.

Yksi tämän hankkeen näkyvimmistä uusista tuloksista on RTI-GPT eli tekoälyavustaja, joka on perehdytetty raportin aineistoon. Sitä voi pitää keskustelevana oppaana, joka johdattaa kiinnostuneet raportin ja sen noin 2 000-sivuisen liiteaineiston äärelle: lukijan ei tarvitse itse etsiä oikeaa kohtaa pitkästä PDF:stä, vaan hän voi kysyä omin sanoin, mitä aineisto kertoo esimerkiksi jostakin teknologiasta, toimialasta, yrityksestä, säädöshankkeesta tai yhteiskunnallisesta ilmiöstä. Tekoälyavustaja voi muodostua raporttikokonaisuuden käytetyimmäksi käyttöliittymäksi, jopa suositummaksi kuin varsinainen PDF-raportti. Tämä on merkittävä muutos siinä, miten ennakointitietoa voidaan käyttää. Vaikka raportin tietopohja ei päivity automaattisesti, RTI-GPT tekee raportin aineistosta vuorovaikutteisen, sillä se voi vastata käyttäjän kysymyksiin ja käyttäjän pyynnöstä myös verrata raportin tuloksia annettuun aineistoon tai internetlähteeseen. Varsinainen raportti ei kykene keskustelemaan analyysiin, mutta RTI-GPT kykenee.

Kun radikaalien teknologioiden ennakointi käynnistyi vuonna 2012, tutkijoille esitettiin toive, että kehitettävä menetelmä saisi joskus sykkivän sydämen ja pystyisi päivittymään automaattisesti. Silloin ajatus oli enemmän suunta kuin todellinen mahdollisuus. Nyt olemme lähempänä sitä kuin tuolloin osattiin kuvitella. Menetelmä voi vahvistua, nopeutua ja tulla elävämmäksi, mutta se tarvitsee edelleen ihmisiä, jotka ymmärtävät, mitä kysyä, mitä epäillä ja mihin johtopäätöksiin kannattaa lopulta sitoutua.

Tulevaisuusvaliokunta julkaisi ennen tätä nyt käsillä olevaa julkaisua RTI-raportin humanoidiroboteista. Se oli eräänlainen menetelmällinen välivaihe: siinä RTI-ajattelutapaa ei sovellettu sataan teknologiaan, vaan poikkeuksellisen syvälle yhteen nopeasti kehittyvään teknologiaperheeseen. Samalla testattiin käytännössä, miten tekoäly voi auttaa jäsentämään teknologian yhteiskunnallisia vaikutuksia, mahdollisuuksia ja riskejä. Nyt vuonna 2025 pilotoitu tekoälyavusteinen työskentelytapa on laajennettu takaisin koko RTI-rungon tasolle tarkastelemaan sataa teknologiaa, 20:tä arvonluontiverkostoa ja koko yhteiskunnallista muutосkenttää.

RTI-työn yhteydessä on katsottu myös taaksepäin ja kysytty yksinkertainen, mutta tärkeä kysymys: etenivätkö aiemmissa ennakoinneissa korkeimmalle nostetut teknologiat todella muita nopeammin? Vastaus näyttää olevan ”kyllä”.

Ensimmäisistä, vuoden 2013 RTI-ennakointituloksista tehtiin vuonna 2016 väliarvio. Silloin todettiin, että vaikuttavimmiksi ennakoitujen teknologioiden yläneljännes oli kehittynyt kolmessa vuodessa nopeammin kuin seuraavaksi ylin neljännes, joka taas oli kehittynyt kolmatta nopeammin, ja niin edelleen.

Vuoden 2018 ennakkoinnista ei tehty vastaavaa virallista väliarviota, mutta tätä esipuhetta varten toteutettiin tekoälyavusteinen tarkastelu siitä, miten nuo kahdeksan vuotta sitten arvioitut teknologiat olivat kypsyneet ja kehittyneet ja miten niiden merkitys oli kasvanut tähän mennessä. Tarkastelussa ei arvioitu teknologioiden nykyistä tasoa, vaan niiden etenemistä eli sitä, kuinka nopeasti ne olivat vuoden 2018 jälkeen parantuneet kyvyiltään, lähestyneet markkinavalmiutta, yleistyneet käytössä tai kasvaneet yhteiskunnallisessa merkityksessään. Jokaisen sadan teknologian etenemisnopeutta kuvattiin asteikolla 0–10, ja näitä arvoja verrattiin vuoden 2018 alkuperäiseen luokitukseen, jossa neljä tähteä tarkoitti vaikuttavimmaksi ennakoitua 25 teknologian ryhmää, kolme tähteä seuraavaksi vahvinta 25 teknologian ryhmää ja niin edelleen.

Tekoälyavusteinen tarkastelu otti lähtökohdaksi vuoden 2018 raportin teknologiakuvaukset. Sitä tuettiin valikoiduilla ajantasaisilla verkkolähteillä niillä alueilla, joilla kehitys oli ollut erityisen nopeaa tai epävarmaa. Tulos oli samansuuntainen kuin vuoden 2016 väliarviossa: vuonna 2018 vaikuttavimmaksi ennakoitu neljännes oli kehittynyt vuoteen 2026 mennessä toista neljänneestä voimallisemmin, ja myös muut neljännekset etenivät odotetussa järjestyksessä. Kansankielisesti sanottuna vuosina 2013 ja 2018 kärki ei siis ollut vain lista kiinnostavista ideoista, vaan se osui molemmilla kerroilla hyvin niihin teknologioihin, jotka todella lähtivät kovimpaan juoksuun. Tämä antaa hyvän perusteen olettaa, että myös tämän raportin kärkijoukko, erityisesti vaikuttavimmaksi arvioitu 25 teknologian ryhmä, sisältää todennäköisesti ne kohteet, joiden etenemistä kannattaa seurata kaikkein tarkimmin.

Raporttia voi lukea kahdella tavalla. Yksi lukija haluaa ehkä aloittaa teknologioista: siitä, mitä uusia läpimurtoja on näkyvissä, miten nopeasti ne voivat kypsyä ja miksi juuri ne on nostettu mukaan sadan joukkoon (tulosten yhteenveto 2, täydelliset tulokset liitteessä 2). Toinen lukija taas haluaa ehkä aloittaa yhteiskunnasta: siitä, miten liikenne, oppiminen, terveys, työn organisointi, vallan rakenteet tai tiedon hankkiminen voivat muuttua tulevina vuosina (tulosten yhteenveto 1, täydelliset tulokset liitteessä 3). Molemmat lukutavat ovat perusteltuja. Juuri siksi RTI-menetelmä on rakennettu kahden näkökulman varaan: teknologioita ei ymmärretä ilman yhteiskuntaa, eikä yhteiskunnallista muutosta voi ymmärtää ilman teknologioita.

Ennen kaikkea raportin tulokset pakottavat katsomaan laajempaa kuvaa eikä vain yksittäisiä innovaatioita. Usein teknologiakeskustelu typistyy siihen, mikä uusi sovellus, laite tai järjestelmä näyttää kiinnostavalta juuri nyt. Tämä raportti pyrkii kysymään vaikeamman, mutta tärkeämmän kysymyksen: mitä tapahtuu, kun useat teknologiat kypsyvät samanaikaisesti, kytkeytyvät toisiinsa ja alkavat muuttaa yhteiskunnan perusrakenteita, työnjakoa, osaamistarpeita, valtasuhteita ja turvallisuuden ehtoja? Juuri tällaisen kokonaiskuvan vuoksi raportti on hyödyllinen. Se auttaa näkemään, missä uudet mahdollisuudet avautuvat, missä kehityksen pullonkaulat sijaitsevat ja missä riskit voivat kasvaa huomaamatta liian suuriksi.

Toivomme, että tätä raporttia luetaan uteliaasti, mutta myös vastuullisesti. Ennakkoinnin tarkoitus ei ole antaa lopullisia vastauksia, vaan auttaa kysymään oikeita kysymyksiä ajoissa. Jos tämä raportti ja sitä täydentävä RTI-GPT tukevat parempaa

keskustelua, parempaa valmistautumista ja viisaampaa päätöksentekoa, ne ovat täyttäneet tehtävänsä. Tulevaisuus ei synny itsestään. Sitä rakennetaan valinnoilla, ja juuri siksi meidän on pyrittävä ymmärtämään mahdollisimman hyvin, millaisten teknologisten murrosten keskellä nuo valinnat tehdään.

”Valitaan suunta.”

Sinuhe Wallinheimo (kok.)

# Dear reader,

You are reading a report that is intended to be more than a review of new technologies. Its purpose is to help us pause and consider how rapidly the world around us is changing, and why that change should be examined seriously even before its consequences become visible everywhere in our everyday lives. This is precisely why the foresight of radical technologies has long been important work for the Committee for the Future of the Parliament of Finland. We have wanted to understand in good time which technologies may profoundly change the way society functions, in what order these changes may unfold, and what kinds of questions decision-making should be able to answer before it is too late.

This report continues the development of the so called Radical Technology Inquirer method (RTI) that has been carried out since 2013. From the outset, the basic idea behind the work has been ambitious: we do not merely list interesting technologies, but seek to build an overall picture of them that is useful for legislators, researchers, companies, teachers, authorities and citizens. The future cannot be governed unless one first tries to grasp it. That is why this report, too, starts from the same ambitious objective as before: to identify one hundred anticipated radical technologies whose impacts may extend widely across different functions of society, and to examine them through twenty value-creation networks.

This time, however, the work includes something essentially new. Generative artificial intelligence has become part of the research process in a way that would have seemed unrealistic only a few years ago. It has been important to see in practice where AI can help in reviewing extensive bodies of material, structuring technological clusters, producing source-based descriptions and anticipating impacts. At the

same time, it has been just as important to see its limits. AI does not replace judgement, responsibility or research-based assessment. For this reason, perhaps the most important methodological lesson of this report is that good foresight can be strengthened with the help of AI, but it cannot be outsourced to AI.

One of the most visible new outcomes of this project is RTI-GPT, an AI assistant trained on the material of the report. It can be thought of as a conversational guide to the report and its approximately 2,000 pages of appendix material: the reader does not need to search for the right section in a long PDF, but can ask in their own words what the material says about, for example, a technology, sector, company, legislative initiative or societal phenomenon. It may become the most widely used interface to the report, even ahead of the actual PDF report. This is a significant change in how foresight knowledge can be used. RTI-GPT makes the report's knowledge base interactive: it can answer users' questions and, at the user's request, also examine material provided by the user or a source indicated on the internet in relation to the report's foresight results. The actual report does not provide this kind of conversational analysis, but RTI-GPT makes it possible.

When this work began in 2012, the researchers were presented with the hope that the method might one day acquire a beating heart and be able to update its foresight results automatically. At that time, the idea was more of a direction than a real possibility. Now we are closer to it than we were then able to imagine. The method can become stronger, faster and more alive, but it still needs people who understand what to ask, what to question and which conclusions are ultimately worth committing to.

The present publication was preceded by the Committee for the Future's RTI report on humanoid robots, published in 2025. It was a kind of methodological intermediate stage: in it, the full RTI approach was not applied to one hundred technologies, but exceptionally deeply to one rapidly developing technology family. At the same time, the report tested in practice how AI can help analyse the societal impacts, opportunities and risks of a technology. That experiment has now been expanded back to the level of the full RTI framework: an examination of one hundred technologies, twenty value-creation networks and the entire field of societal change.

In connection with the RTI work, we have also looked back and asked a simple but important question: did the technologies ranked highest in earlier foresight exercises really advance faster than the others? The answer appears to be yes.

An interim assessment of the first RTI foresight results from 2013 was carried out in 2016. At that time, it was found that the top quartile of technologies anticipated in 2013 to have the greatest impact had developed over four years faster than the next highest quartile, which in turn had developed faster than the third quartile, and so on.

No corresponding official interim assessment has been carried out for the 2018 foresight exercise, but for this foreword an AI-assisted review was conducted of how the technologies assessed eight years ago have developed, matured and grown in significance up to the present day. The review did not assess the current level of the technologies, but rather their rate of progress: how quickly they have improved in capability since 2018, approached market readiness, become more widely adopted or grown in societal significance. Each of the one hundred technologies was given an assessment of this rate of progress on a scale from 0 to 10, and these assessments were compared with the original 2018 classification, in which four stars referred to the group of 25 technologies anticipated to have the greatest impact, three stars to the next strongest group of 25 technologies, and so on.

The AI-assisted review was based on the technology descriptions in the 2018 report and supported with selected up-to-date online sources in areas where development has been particularly rapid or uncertain. Its result was similar to that of the 2016 interim assessment: by 2026, the quartile anticipated in 2018 to have the greatest impact had developed more strongly than the second quartile, and the other quartiles also progressed in the expected order. In plain language, the leading technologies identified in 2013 and 2018 were not merely lists of interesting ideas; on both occasions, they successfully identified the technologies that truly set off at the fastest pace. This provides good grounds to assume that the leading group in this report as well, especially the group of 25 technologies assessed as having the greatest impact, is likely to contain the development paths whose progress should be monitored most closely.

The report can be read in two ways. One reader may wish to begin with the technologies: what new breakthroughs are visible, how quickly they may mature, and why these particular technologies have been included among the one hundred. This is covered in Summary of Results 2, with the complete results in Appendix 2. Another reader may wish to begin with society: how transport, learning, health, the organisation of work, structures of power or the acquisition of knowledge may change in the coming years. This is covered in Summary of Results 1, with the complete results in Appendix 3. Both ways of reading are justified. This is precisely why the RTI method is built on two perspectives: technologies cannot be understood without society, and societal change cannot be understood without technologies.

The significance of the results lies above all in the fact that they force us to look beyond individual innovations and consider the broader picture. Technology discussions are often reduced to which new application, device or system happens to seem interesting at the moment. This report seeks to ask a more difficult but more important question: what happens when several technologies mature simultaneously, connect with one another and begin to transform the basic structures of society, the division of labour, competence needs, power relations and the conditions of security? This kind of overall picture makes the report useful. It helps us see where new opportunities are opening up, where the bottlenecks of development are and where risks may grow unnoticed until they become too large.

We hope that this report will be read with curiosity, but also with responsibility. The purpose of foresight is not to provide final answers, but to help ask the right questions in time. If this report and the accompanying RTI-GPT support better discussion, better preparedness and wiser decision-making, they will have fulfilled their purpose. The future does not emerge on its own. It is built through choices, and that is precisely why we must strive to understand as well as possible the kinds of technological transformations amid which those choices are made.

“Let us choose a direction.”

#### **THE TECHNOLOGY FORESIGHT STEERING GROUP OF THE COMMITTEE FOR THE FUTURE**

Ville Vähämäki, Chairman (Finns Party)

Timo Harakka (Social Democratic Party of Finland)

Ville Kaunisto (National Coalition Party)

Sheikki Laakso (Finns Party)

Sinuhe Wallinheimo (National Coalition Party)

# Introduction

The pace of technological development has grown unusually fast, uneven, and difficult to interpret. Technical breakthroughs, commercial scaling, regulatory reactions, and geopolitical tensions now interact in ways that can alter everyday life in a relatively short period of time. For this reason, the societal significance of radical technologies should not be assessed only through their technical novelty or market prospects. Their importance lies equally in their capacity to reorganize infrastructures, institutions, power relations, work, and everyday practices. In some cases, such reorganization may open new possibilities for productivity, health, accessibility, or sustainability. In other cases, it may intensify concentration of power, insecurity, exclusion, or conflict. From a foresight perspective, the issue is therefore not whether technological change will be consequential, but how its consequences will be distributed, governed, and interpreted.

Recent years have made this particularly visible. Large-scale disruptions have shown how rapidly sociotechnical change can reshape ordinary life, public authority, international dependencies, and the boundaries between resilience and vulnerability. Broad technological and sociotechnical trajectories can help explain why major disruptions may emerge faster, spread wider, and affect daily life more deeply than societies often anticipate. It is in this sense that the present report is situated between two competing horizons: one in which technological development supports broader flourishing, and another in which the same developments deepen fragility, asymmetry, and coercion. The future remains open, and the stakes of technological foresight are high.

## What was the task

The task of the present report was to produce an updated foresight summary of anticipated radical technologies and their wider societal implications by applying and refining the Radical Technology Inquirer (RTI) methodology. In substantive terms, the report identifies and organizes one hundred anticipated radical technologies (ARTs) into twelve technology groups and examines their possible implications across twenty global value-producing networks (GVNs). In methodological terms, the report continues to renew RTI with the help of generative AI. The present exercise therefore has a dual purpose. First, it provides an updated picture of the technological developments most likely to shape future societal transformations. Second, it examines how far AI can support a full RTI-style foresight process when used under explicit analytical constraints.

For that reason, the report is not only a summary of technological developments. It is also an attempt to update the practical conditions under which technology foresight can be carried out. The question is not merely which technologies matter, but how such technologies can be identified, described, evidenced, and related systematically to societal transformation in a research environment where both the speed of technological change and the availability of generative AI have increased substantially.

## How the task was carried out

The work was carried out as a continuation of the RTI method rather than a wholly new foresight framework. The underlying idea remained the same as in earlier RTI reports: anticipated radical technologies were identified and described, and their significance was then assessed in relation to broad societal value-producing networks. However, the route by which the present report arrived at its final technology, and the impact set differed from earlier rounds. In the 2018 RTI report (Linturi & Kuusi 2018), the source base and technology baskets were built through extensive crowdsourcing and expert-supported processing. To assess the compatibility of generative AI with the RTI method, a pilot study was carried out in 2025 (Björkroth et al. 2025). In the pilot, the foundational work on just one ART, humanoid robots, was conducted manually by researchers and then extended with AI-assisted analysis. At that stage, AI proved useful in societal impact analysis. In the present study, the newly launched research features of generative AI enabled its use also in the earlier phases of the process: in identifying candidate domains for the full range of 100 ARTs, in generating and refining prospect ARTs, in expanding the descriptions of those technologies, in producing evidence dossiers, and in supporting ART-by-GVN impact analysis. In practical terms, an AI-assisted “full iteration” of RTI only became viable quite recently, when Deep Research-type model functions became available. Earlier generative AI tools could support selected phases of the process, as seen in the 2025 pilot, but not yet the source-grounded and sufficiently systematic handling of a full-spectrum RTI round at this scale. Despite the extensive use of AI,

the process in this present remained researcher-led in all decisive respects, with the research team curating candidate technologies, checking evidence dossiers, and interpreting and refining the resulting analyses. The report should therefore be understood as an AI-assisted RTI process, not an automatically generated outlook.

The present report also differs from the 2025 pilot in one further respect. Whereas the pilot investigated in depth one anticipated radical technology and its implications across the value creation networks, the current report returns to a broader system-level horizon. It therefore asks not only which individual technologies may become significant, but also how several technological developments may advance and mature in parallel, reinforcing or counteracting one another, and alter the conditions under which societies produce value, exercise power, and interpret risk.

## How to read the results

The results of this report should be read as structured foresight, not as prediction. The report does not claim that all listed technologies will mature exactly as described, nor that each identified impact will materialize in a linear way. Rather, the purpose is to identify plausible directions of change, clarify where transformation pressures may be accumulating, and make visible the kinds of societal effects that may otherwise remain unnoticed until they are already well underway. The report is therefore best read as an analytical map of emerging possibilities, tensions, and dependencies. Its value lies less in point prediction than in systematic comparability across technologies and societal domains.

The twelve technology groups should be understood as organizing devices that make a broad set of anticipated radical technologies easier to interpret. They do not imply that technological change proceeds neatly inside group boundaries. On the contrary, many of the most important future effects are likely to arise precisely through combinations across groups, for example between sensing, AI, robotics, energy systems, standards, and digital platforms. Similarly, the twenty value-producing networks should not be read as isolated sectors. They are analytical models of broad societal functions, and their purpose is to show how technological change may shift the dominant and challenger regimes through which value is created. Many technologies therefore appear significant not only because of their direct use, but because of their institutional, economic, political, or cultural spillovers across several networks at once.

For this reason, the results should be read not only as a comparison of individual technologies, but as a structured estimate of their combined societal reach and plausibility. In RTI-methodology, the total significance of an anticipated radical technology is based on the sum of its impacts across all twenty value-producing networks, weighted by its maturity. The highest-ranking technologies are therefore not simply those that seem most dramatic in one field, but those whose effects spread across several networks and whose maturity makes those effects plausible within the assessment horizon. The ranking follows this logic because technologies with

broad horizontal effects often change society most deeply: by cutting across several domains at once, they can generate entirely new verticals, meaning new sectors, markets, and institutional arrangements. High total scores thus reflect breadth, intensity, and practical readiness. Lower scores, by contrast, may reflect narrower applicability or earlier maturity rather than lack of significance as such.

This report can be approached from two complementary directions. A reader primarily interested in broader societal change may begin with the twenty global value-producing networks (GVNs), where the emphasis is on how technological development may reshape the dominant and challenger regimes through which value is created in society (Summary of results 1). A reader primarily interested in technological change may begin with the twelve technology groups and the one hundred anticipated radical technologies (ARTs) organized under them (Summary of results 2).

The ART sections present 100 anticipated radical technologies as bottleneck-oriented technology bundles. Their purpose is not only to describe individual technologies, but to identify the kinds of capability shifts that may remove important technical, economic, institutional, or operational constraints across several domains at once. Organizing the ARTs into technology groups aims to help the reader see broader patterns and connections between related ARTs, while the individual ART entries in attachments provide a more specific picture of what each technology bundle consists of and why it matters.

The GVN sections approach the same material from the opposite direction. Instead of starting from technologies, they start from broad societal functions such as transport, logistics, health care, acquiring information, or power structures. Their purpose is to describe plausible transformations in the way value is created, organized, and contested in these domains, and to show how different anticipated radical technologies may contribute to those transformations.

## How to use the Appendices

The main research material is contained in the appendix section of this report. The first attachment summarizes the anticipated impact of the 100 ARTs on 20 GVNs in a table form. In Attachment 2, each anticipated radical technology (ART) is presented in detail, together with source references, a maturity assessment, and its expected fields of impact. Attachment 3 displays the anticipated societal impacts of the ARTs on GVNs, starting from the passenger transport GVN and ending in power structures GVN. The ART descriptions that were used as reference when gathering the evidence for ARTs can be found from Attachment 4. The GVN descriptions that were used as reference when anticipating the societal impacts of ARTs can be found from Attachment 5. Scoring criteria for ART maturity and ART/GVN impact are included in Attachment 6.

The appendix material has been designed first and foremost to be read by AI systems. Any interested reader can, of course, also consult it directly for details, reasoning, and source references. The most convenient and intended way to use the material, however, is to make it available to an AI system. Due to the length and structure of the material, to be useful, generative AI needs understanding of the knowledge architecture of the report – a map helping it to know what kind of information can be found and where it can be found. This places requirements on the AI. It needs capability to use the supplied instructions and act accordingly. Several contemporary AI systems are widely available, each with their own user interfaces. ChatGPT with its Custom GPT feature is the most common.

To enable such use with customized AI, the research material structure has been standardized so that related content can be located without having to read the entire appendix section from beginning to end. The AI-oriented appendix package is available at <https://www.eduskunta.fi/en/members-and-parliamentary-bodies/committees/committee-for-the-future/radical-technology-inquirer-rti> and it includes a Readme.txt file that provides an illustrative guide to using the material with ChatGPT, the service most used in Finland. In principle, the package enables the user to build their own RTI-GPT with any AI model of their choice. It should be kept in mind, however, that the quality of answers differs by the model even when the database and GPT instructions are identical.

## Introducing the Radical Technology Inquirer GPT (RTI-GPT)

Even though such development work was not originally planned, one of the report's authors, Risto Linturi, created and shared an example of how the full research dataset behind this report can be explored via customized RTI-GPT. The readers are encouraged to try this with a free ChatGPT account either by opening this link, [RTI-GPT \(FIN\)](#) for a Finnish language version, [RTI-GPT \(ENG\)](#) for an English language version, or by selecting the Custom GPT called **Radical Technology Inquirer –GPT (Fin)** or **Radical Technology Inquirer –GPT (Eng)** within ChatGPT. Use requires logging in ChatGPT. ChatGPT was chosen as a platform for the model experiment because it enabled (at least in spring 2026), free sharing of links to user-created customized GPTs. It should be noted that at the time of publication, free registered use enables just the basic thinking mode of RTI-GPT, which is sufficient for exploring the content of the report. More in-depth insights can be generated, however, by using extended thinking mode. Detailed instructions for using this RTI-GPT can be obtained simply by asking it from RTI-GPT itself. Questions or requests may concern any area of life, technology, or society. The answers produced by RTI-GPT are based primarily on the research material provided to it. For that reason, its answers are most precise and least open to interpretation when the user refers to the GVN and ART names used in the report, although this is not required.

The questions can be very broad. For example, both the Summary of results 1 (GVN) and Summary of results 2 (ART) in this summary report were each produced with a single RTI-GPT prompt. Questions may also refer to external sources. One may, for example, ask for an account of the most likely transformation of passenger transport and request that the system read the Finnish online legal database Finlex to identify the main legislative barriers and bottlenecks affecting that transformation. It is also possible to ask RTI-GPT to study company websites, professional groups, or schools of thought and ask for an assessment of how they are likely to fare in the future. Such possibility to cross reference external sources from the perspective of RTI seems to yield useful answers that it was included in RTI-GPT despite the drawback that RTI-GPT may then also allow low quality material to influence its answers if user is not careful in formulation their queries. To help the user to understand the nature of RTI-GPT and to formulate relevant prompts, RTI-GPT is instructed to clearly indicate what part of its response is based on its database, what comes from the user-appointed sources and what it found from the internet. As with all GPTs, it is better to start a new discussion when changing the topic.

It should be remembered, however, that RTI-GPT is a language model and that it interprets foresight material in its own way. The future is not easy to predict, unless one is speaking of the orbits of planets and stars. Foresight is therefore inherently uncertain, and AI will certainly make mistakes in it as even the most experienced humans do. Even so, an AI equipped with a systematic framework and a broad research base of this kind is clearly of great interest and can generate many fresh perspectives worthy of consideration.

# Summary of results 1: anticipated transformations in 20 global value-producing networks

This is a summary from the results in Attachment 3: Anticipated GVN Impacts of ARTs and Attachment 5: GVN descriptions used in ART impact assessment. The summary describes and evaluates the potential transformation of each global value-producing network used to describe societal functions in the RTI-methodology. Key technologies anticipated to drive the transformation are listed. Further extensively detailed analysis how each ART may impact each GVN can be found in Attachment 3.

The impact scores mentioned in the ART lists are logarithmic (possible values are 0, 1, 3, 5, 10 or 20). For more detailed impact score criteria, see Attachment 6.

This summary was created by using the RTI-GPT.

# GVN 1 – Passenger Transport

## KEY CONCLUSION

The core transformation in GVN 1 is a shift from ownership-based mobility toward networked, service-based and partly autonomous mobility solutions. The change is not only technical: it also affects urban structure, the logic of ownership, and who coordinates traffic. The strongest challenger-regime dynamic emerges when vehicles, infrastructure, connectivity, payment and AI-based control increasingly operate as one system rather than as separate layers. The key uncertainty is whether the result will be a more efficient shared mobility regime or an even more tightly controlled platform regime.

## UNDERLYING LOGIC OF THE GVN

GVN 1 is organized around moving people from one place to another safely, efficiently, comfortably, freely and at reasonable cost. The current dominant regime rests on private car use, the infrastructure that supports it, and schedule-based public transport. Its strength lies in flexibility and the deep cultural, spatial and economic embedding of private cars, but the model also creates underutilized assets, large parking needs, emissions, and exclusion of those who cannot drive. The challenger regime rests on autonomous vehicles, Mobility as a Service models, shared mobility, electric solutions and more precise digital infrastructure. This suggests that the pressure for change is directed not only at vehicles but at the entire logic of mobility: how trips are bought, combined, allocated and coordinated. The central conflict is therefore not simply car versus bus, but privately controlled mobility versus service-based and increasingly system-coordinated mobility.

## ANTICIPATED DIRECTION OF TRANSFORMATION

The likely direction is toward higher utilization rates, service-based models, and continuous coordination. The main benefits are efficiency, safety, lower costs, lower emissions, and better accessibility. This points to passenger transport moving away from one person controlling one vehicle at a time toward systems that allocate capacity, routing and responsibility far more dynamically.

The change may also be discontinuous in places. Once usable autonomy, reliable connectivity and interoperable control infrastructure converge with mature regulation, part of today's ownership and parking logic may lose its foundation quickly. What remains uncertain is how quickly consumers accept the loss of direct control, how cities redistribute street and parking space, and whether public transport is strengthened or weakened in the transition.

## ESTIMATED PACE OF TRANSFORMATION

- 2018–2026: moderate. Many drivers — electrification, persistent connectivity, platforms and AI-assisted coordination — have already moved from pilot projects into practice, but legal liability, safety requirements and inherited infrastructure slow the broader shift.

- 2026–2045: fast and potentially discontinuous. If autonomy, reliable oversight, and service-based coordination become established, the shift may accelerate clearly between 2026 and 2045 because both the cost structure and the use of space will change at the same time.

## **MOST INFLUENTIAL ARTS FOR THIS GVN**

- ART 05.029 Self-Driving Vehicles — impact score in GVN 1: 20 — shifts decision and control capacity from the human driver to the system; in this GVN it strengthens service-based mobility, automation, and networked control.
- ART 01.001 Global Broadband Connectivity — impact score in GVN 1: 10 — builds a near-ubiquitous connectivity layer; in this GVN it strengthens service-based mobility, automation, and networked control.
- ART 03.017 Trustworthy AI Systems — impact score in GVN 1: 10 — makes the use of AI more auditable and institutionally acceptable; in this GVN it strengthens service-based mobility, automation, and networked control.
- ART 03.019 Collaborative Multi-Agent AI — impact score in GVN 1: 10 — enables coordinated action among many machines, software systems and actors; in this GVN it strengthens service-based mobility, automation, and networked control.

## **GVN SUMMARY**

GVN 1 is strategically important because it brings together infrastructure, energy, data, regulation, and everyday accessibility. The change seems to advance first in layers and then potentially by leaps if service-based and autonomous logic starts to outcompete the ownership-based model. The greatest uncertainty is whether safety, liability, and social acceptance can be resolved in a sufficiently credible way.

## **GVN 2 – Logistics**

### **KEY CONCLUSION**

The core transformation in GVN 2 is the shift from linear supply chains to continuously visible, software-directed, and partly autonomous networks of goods flows. The change is structural because it simultaneously affects transport, storage, packaging, distribution, and the role of the consumer. The strongest drivers are collaborative AI coordination, autonomous transport solutions, persistent connectivity and traceability. The direction of change is toward faster, more granular and more home-linked logistics.

### **UNDERLYING LOGIC OF THE GVN**

GVN 2 is organized around moving goods, materials, equipment, animals and waste from one place to another easily, accurately, flexibly and cost-effectively. The current dominant regime is built around industry- and trade-centered logistics, shared transport infrastructure, containerization, large shipment sizes, and the consumer's

own pickup work. This favors large actors, standardized packaging, and deeply established distribution channels.

The challenger regime is based on smart robotization, autonomous vehicles and drones, individually identifiable packaging, digital platforms, cloud services, and shared smart lockers. This suggests that the change in logistics is not only a transport shift but also a shift in information, traceability, and exception management.

## **ANTICIPATED DIRECTION OF TRANSFORMATION**

The likely direction is toward real-time synchronized goods flows, smaller shipment sizes, more automated sorting and a more direct link between manufacturer, distributor and end user. The main benefits are smoother distribution, better availability in sparsely populated areas, less waste, and stronger competition. This suggests that a competitive advantage in logistics is shifting increasingly toward the ability to see and steer the whole network rather than simply manage a single transport leg.

The change may move faster than in many other GVN areas because logistics immediately reward solutions that improve efficiency and precision. It remains unclear how far labor-market effects, cybersecurity risks, and the governance of urban space will limit large-scale deployment, even though they clearly appear as constraints.

## **ESTIMATED PACE OF TRANSFORMATION**

- 2018–2026: moderate but accelerating. Recent years have strengthened platforms, visibility, and automation, but the reordering of the whole network has been uneven and concentrated among large actors.
- 2026–2045: fast. By 2045, logistics appears likely to benefit especially strongly from multi-agent coordination, autonomy and traceability, so the change may spread rapidly across the whole chain.

## **MOST INFLUENTIAL ARTS FOR THIS GVN**

- ART 03.019 Collaborative Multi-Agent AI — impact score in GVN 2: 20 — enables coordinated action among many machines, software systems and actors; in this GVN it strengthens a real-time coordinated and visible logistics network.
- ART 05.029 Self-Driving Vehicles — impact score in GVN 2: 20 — shifts decision and control capacity from the human driver to the system; in this GVN it strengthens a real-time coordinated and visible logistics network.
- ART 12.093 Global Supply Chain Traceability Networks — impact score in GVN 2: 20 — makes the origin of materials, components and supply chains more auditable; in this GVN it strengthens a real-time coordinated and visible logistics network.
- ART 01.001 Global Broadband Connectivity — impact score in GVN 2: 10 — builds a near-ubiquitous connectivity layer; in this GVN it strengthens a real-time coordinated and visible logistics network.

## **GVN SUMMARY**

GVN 2 is strategically important because it acts as the backbone of material and informational movement across other networks. The change looks set to accelerate as visibility, traceability and automation converge. The greatest uncertainty is whether work, responsibility and safety change in a controlled way or whether logistical efficiency is achieved at the cost of new vulnerabilities.

## **GVN 3 – Manufacturing of Goods**

### **KEY CONCLUSION**

The core transformation in GVN 3 is the shift from centralized mass production toward more flexible, partly distributed and digitally directed manufacturing. The change is above all a change in production structure: design, manufacturing, standardization, and distribution are being reconnected in new ways. The strongest drivers are agile factories, humanoid robots, manufacturing-specific standardization, and collaborative AI coordination. The direction is not a full departure from economies of scale, but a new combination of scale and customization.

### **UNDERLYING LOGIC OF THE GVN**

GVN 3 is organized around producing physical goods and equipment in ways that are functional, high-quality, cost-effective, and suited to user needs. The current dominant regime rests on large industrial facilities, global centralization, subcontracting chains, mass production, and hierarchical distribution. It is supported by norm-based governance, risk aversion, and the separation of design from production.

The challenger regime is built on robotization, digital manufacturing, 3D printing, AI-assisted design, flexible lines, and digital manufacturing chains. This suggests that the core of the change is not only a new machine base, but also production moving closer to use, maintenance, and rapid iteration.

### **ANTICIPATED DIRECTION OF TRANSFORMATION**

The anticipated direction is toward production in which variation, short runs, and local adaptation are economically feasible more often than before. The main benefits are lower inventory and logistics needs, easier repair, more local employment, and less vulnerability to global disruption. On this basis, manufacturing is gradually shifting from pure volume optimization toward responsiveness and model-based control.

The change is likely to be uneven. Large and safety-critical manufacturing environments will remain heavily standardized for a long time, while the production of smaller series, spare parts, and configurable products may change quickly. It remains unclear how far intellectual property rights, liability issues, and quality assurance will ultimately limit genuinely distributed manufacturing.

## ESTIMATED PACE OF TRANSFORMATION

- 2018–2026: moderate. Digital design, robotics and software-defined production control have strengthened clearly, but the traditional logic of scale and quality remains strong.
- 2026–2045: moderate but accelerating. By 2045, the shift is likely to deepen because flexible automation, certified interoperability, and the modularity of production reinforce one another.

## MOST INFLUENTIAL ARTS FOR THIS GVN

- ART 06.039 Reconfigurable & Agile Factories — impact score in GVN 3: 20 — makes production more rapidly reconfigurable; in this GVN it strengthens flexible, digital and partly distributed manufacturing.
- ART 12.100 Manufacturing-specific Standards, Conformance Testing & Certification Infrastructure — impact score in GVN 3: 20 — standardizes production quality, testing and certification practices; in this GVN it strengthens flexible, digital and partly distributed manufacturing.
- ART 05.031 Humanoid and General-Purpose Robots — impact score in GVN 3: 20 — brings general-purpose robotics into environments designed for humans; in this GVN it strengthens flexible, digital and partly distributed manufacturing.
- ART 06.038 Digital Twin & Simulation-Driven Production — impact score in GVN 3: 10 — turns the state of production and infrastructure into something that can be continuously simulated and optimized; in this GVN it strengthens flexible, digital and partly distributed manufacturing.

## GVN SUMMARY

GVN 3 is strategically important because it determines how quickly society can turn design into physical production. The change is likely to advance in layers: first in information-intensive and high-value segments, and later more broadly. The greatest uncertainty is how strongly quality, liability, and IP issues ultimately slow decentralization.

## GVN 4 – Sustenance

### KEY CONCLUSION

The core transformation in GVN 4 is the shift from standardized food production based on long chains toward a more personalized, local, and biotechnologically diversified food system. The change matters because it simultaneously affects health, sustainability, security of supply, and everyday habits. The strongest drivers are cellular agriculture, synthetic biology, traceability and automated coordination, but consumer behavior remains the decisive bottleneck. The direction is clear, but the pace depends on acceptance and changes in distribution channels.

## UNDERLYING LOGIC OF THE GVN

GVN 4 is organized around securing the supply of energy, nutrients, and trace elements for humans and pets. The current dominant regime rests on traditional agriculture, animal production, industrial processing, distribution channels dominated by retail chains, and strong regulation and control. The values of this system emphasize economies of scale, safety, and the preservation of existing structures.

The challenger regime is built around indoor farming, urban production, biotechnological food production, insect protein, robot kitchens, and new methods that extend shelf life. This suggests that the food system is beginning to split: one part continues to industrialize, while another moves closer to the consumer and to individual needs.

## ANTICIPATED DIRECTION OF TRANSFORMATION

The anticipated direction is toward food that is more measurable, more tailored, and logistically more flexible than before. The main benefits are improving public health, lower environmental burden, greater crisis resilience, and new business opportunities. This suggests that the food system may shift away from pure volume logistics toward demand-driven, partly localized, and biologically programmable production.

Technological potential is likely to advance faster than habits and regulation. Challenger-regime solutions may mature quickly in laboratories and limited applications, but the broader shift depends on whether new proteins, gene editing, and automated preparation are accepted as part of everyday food. It remains unclear how quickly major distributors will adopt these models or how sharply consumer perceptions will change.

## ESTIMATED PACE OF TRANSFORMATION

- 2018–2026: slow but strengthening. Many solutions have recently moved from experiments to visible alternatives, but the basic structure of the system still rests heavily on traditional agriculture and retail.
- 2026–2045: moderate but accelerating. By 2045, the shift may strengthen clearly if the benefits for health, sustainability and security of supply begin to outweigh the cultural inertia of traditional food models.

## MOST INFLUENTIAL ARTS FOR THIS GVN

- ART 09.069 Cellular Agriculture & Cultured Meat — impact score in GVN 4: 20 — detaches part of food production from traditional agricultural logic; in this GVN it strengthens a personalized, increasingly local, and more biotechnological food system.
- ART 09.071 Synthetic Biology & Designer Microbes — impact score in GVN 4: 10 — opens the door to biologically designed production and process solutions; in this GVN it strengthens a personalized, increasingly local, and more biotechnological food system.

- ART 12.093 Global Supply Chain Traceability Networks — impact score in GVN 4: 10 — makes the origin of materials, components and supply chains more auditable; in this GVN it strengthens a personalized, increasingly local, and more biotechnological food system.
- ART 03.019 Collaborative Multi-Agent AI — impact score in GVN 4: 10 — enables coordinated action among many machines, software systems and actors; in this GVN it strengthens a personalized, increasingly local, and more biotechnological food system.

## **GVN SUMMARY**

GVN 4 is strategically important because it connects biology, logistics, consumer behavior and crisis resilience. Change appears likely, but uneven. The greatest uncertainty is how quickly acceptance, regulation, and distribution networks adapt to the technological potential.

## **GVN 5 – Energy Supply**

### **KEY CONCLUSION**

The core transformation in GVN 5 is the shift from a centralized and production-heavy energy system toward decentralized, storable, and software-directed energy production and use. The change is clearly structural because it simultaneously affects production, storage, demand flexibility, grids, and fuel production. The strongest drivers are microgrids, storage, and power-to-X solutions, supported by interoperability and multi-actor control. This is one of the fastest-reorganizing GVN areas.

### **UNDERLYING LOGIC OF THE GVN**

GVN 5 is organized around producing, refining, storing, and distributing energy in forms suited to demand. The current dominant regime is based on centralized fossil fuel and nuclear generation, distribution grids, regulated markets, and little interest in storage. Behind it is the need to secure cheap energy, maintain regional price uniformity, and regulation that slows the pace of change.

The challenger regime is built on renewable energy, batteries, synthetic fuels, local production, fuel cells, and new kinds of energy infrastructures. This suggests that energy is increasingly becoming a problem of coordination and control rather than production alone: what matters is not only how much energy is produced, but who can store it, sell it, time it, and use it flexibly.

### **ANTICIPATED DIRECTION OF TRANSFORMATION**

The anticipated direction is toward a modular energy economy in which production, storage, consumption, and transport are linked into a single controllable whole. The main benefits are lower costs, less dependence on centralized infrastructure,

better security of supply, and environmental gains. This suggests that the value of energy is shifting increasingly toward the ability to combine decentralized resources into a reliable system.

In this GVN in particular, technical and institutional change may begin to reinforce one another. The more renewables, storage, and local control solutions are adopted, the harder it becomes for the old model to retain its position. It remains unclear how quickly political resistance, sunk costs, and investment uncertainty will ease in different regions.

### **ESTIMATED PACE OF TRANSFORMATION**

- 2018–2026: moderate but accelerating. Renewables, storage and local control have already changed the logic of energy, even though the centralized system remains strong.
- 2026–2045: fast. By 2045, decentralization, storage and synthetic fuels appear strong enough to reshape both the technical and institutional structure quickly.

### **MOST INFLUENTIAL ARTS FOR THIS GVN**

- ART 08.066 Resilient microgrids — impact score in GVN 5: 20 — decentralizes energy management into local, resilient nodes; in this GVN it strengthens decentralized, storable and software-directed energy.
- ART 08.060 Grid-Scale Energy Storage — impact score in GVN 5: 20 — smooths variation in the power system and enables more flexible usage models; in this GVN it strengthens decentralized, storable and software-directed energy.
- ART 08.062 Green Hydrogen & Power-to-X — impact score in GVN 5: 20 — turns electricity into storable and transportable fuels; in this GVN it strengthens decentralized, storable and software-directed energy.
- ART 12.091 Universal IoT Interoperability Standards — impact score in GVN 5: 10 — lowers the friction of interoperability across device and system ecosystems; in this GVN it strengthens decentralized, storable and software-directed energy.

### **GVN SUMMARY**

GVN 5 is strategically important because nearly all other networks depend on the energy it provides. The change looks accelerating and cumulative. The greatest uncertainty is how quickly political and regulatory structures adapt to the logic of decentralized energy.

## GVN 6 – Materials

### KEY CONCLUSION

The core transformation in GVN 6 is the shift in the materials economy toward lighter, cleaner, more circular and functionally smarter materials. The change is important but more indirect than in many service GVNs, because it proceeds through the performance and resource structure of other networks. The strongest drivers are circularity, materials traceability, manufacturing standards, and new processes. The direction is clear, but the heavy legacy of process industry makes progress gradual.

### UNDERLYING LOGIC OF THE GVN

GVN 6 is organized around producing and refining materials so that they support other production, withstand use and remain economically available. The current dominant regime is based on traditional industrial materials, mass production, global supply chains, and capital-intensive processes. The system is sustained by stability, predictability, and strong existing industrial investments.

The challenger regime emphasizes new lightweight and efficient materials, nano-technology, bio-based solutions, lower-temperature processes, 3D printing, and more efficient recycling. This suggests that materials are gradually shifting from passive raw inputs to infrastructure elements that determine system performance.

### ANTICIPATED DIRECTION OF TRANSFORMATION

The anticipated direction is toward a material system in which origin, reuse, functionality, and the energy efficiency of processes matter more than before. The main benefits are a stronger circular economy, lower environmental burden, and the enabling of new processes. This suggests that the competitiveness of materials is judged less by price alone and more by full lifecycle and system effect.

The change is likely to advance first in applications where a new material brings an immediate performance or regulatory benefit. It remains unclear how quickly old material standards, capital-intensive plants, and global sourcing logic will make room for genuinely new material paradigms.

### ESTIMATED PACE OF TRANSFORMATION

- 2018–2026: slow but strengthening. Many material trends have strengthened, but heavy processes, long approval cycles, and industrial inertia keep the shift slow for now.
- 2026–2045: moderate. By 2045, circularity, traceability, and new standards in production may reinforce the change, but the whole material system will not transform quickly.

## **MOST INFLUENTIAL ARTS FOR THIS GVN**

- ART 06.040 Circular & Sustainable Manufacturing — impact score in GVN 6: 20 — shifts manufacturing toward circularity, repairability, and material efficiency; in this GVN it strengthens a circular and performance-oriented materials economy.
- ART 12.100 Manufacturing-specific Standards, Conformance Testing & Certification Infrastructure — impact score in GVN 6: 20 — standardizes production quality, testing and certification practices; in this GVN it strengthens a circular and performance-oriented materials economy.
- ART 12.093 Global Supply Chain Traceability Networks — impact score in GVN 6: 10 — makes the origin of materials, components, and supply chains more auditable; in this GVN it strengthens a circular and performance-oriented materials economy.
- ART 06.039 Reconfigurable & Agile Factories — impact score in GVN 6: 10 — makes production more rapidly reconfigurable; in this GVN it strengthens a circular and performance-oriented materials economy.

## **GVN SUMMARY**

GVN 6 is strategically important because it defines the resource and cost base of other networks. The change is likely, but structurally heavy. The greatest uncertainty is whether a complementary logic of new materials emerges or a genuinely replacement-oriented industrial logic.

## **GVN 7 – Built Environment**

### **KEY CONCLUSION**

The core transformation in GVN 7 is the shift in the built environment from a slowly changing background to a programmatically maintained, measurable, and partly autonomy-adaptive system. The change is structural, but slower than in many digital GVNs because the built environment is slow, regulated, and long-lived. The strongest drivers are supportive infrastructure for autonomy, construction and maintenance robotics, and digital design. The direction is toward an environment that no longer only reacts to use but begins to anticipate and steer it.

### **UNDERLYING LOGIC OF THE GVN**

GVN 7 is organized around providing people and activities with a usable, safe and fit-for-purpose built environment. The current dominant regime rests on traditional construction methods, tight norm-based governance, centralized decision-making, and design driven by cost and location. Construction and maintenance are still only lightly automated and strongly directed by authorities and professional structures.

The challenger regime emphasizes construction and maintenance robotics, changing mobility solutions, new materials, and advanced building automation. This suggests that the built environment is beginning to shift from a structure that passively supports use to an active service layer that carries energy, data, logistics, and automated movement.

## **ANTICIPATED DIRECTION OF TRANSFORMATION**

The anticipated direction is toward an environment in which automation and sensing are interwoven with design, use, and maintenance. The main benefits are efficiency, easier maintenance, new material solutions, and changing space requirements. This suggests that the built environment is adapting more to moving machines, flexible services, and continuous use of data than to fixed solutions built for a single purpose.

The change is likely to concentrate first in environments where automation brings direct savings or safety benefits: logistics properties, new districts, maintenance-critical sites, and corridors for autonomous traffic. It remains unclear how quickly norms, investment cycles, and local decision-making will allow for a broader system-level shift.

## **ESTIMATED PACE OF TRANSFORMATION**

- 2018–2026: slow. In the logic of this GVN, the built environment is a slow variable: new technologies are visible, but broad structural change is still proceeding slowly.
- 2026–2045: moderate but accelerating. By 2045, the support needs of automation, changes in energy solutions, and the digitalization of maintenance may accelerate the change significantly.

## **MOST INFLUENTIAL ARTS FOR THIS GVN**

- ART 05.034 Supportive Infrastructure for Autonomy — impact score in GVN 7: 20 — builds the physical and digital support layer required by autonomy; in this GVN it strengthens a built environment that supports automation and is guided by data.
- ART 05.029 Self-Driving Vehicles — impact score in GVN 7: 20 — shifts decision and control capacity from the human driver to the system; in this GVN it strengthens a built environment that supports automation and is guided by data.
- ART 03.019 Collaborative Multi-Agent AI — impact score in GVN 7: 10 — enables coordinated action among many machines, software systems and actors; in this GVN it strengthens a built environment that supports automation and is guided by data.
- ART 04.022 Immersive Augmented & Virtual Reality — impact score in GVN 7: 10 — brings experiential and simulated environments into everyday activity; in this GVN it strengthens a built environment that supports automation and is guided by data.

## **GVN SUMMARY**

GVN 7 is strategically important because it locks in the operating possibilities of other networks for a long time. The change appears slow but cumulative. The greatest uncertainty is how much of the new logic can be built on top of the old environment and how much it requires entirely new areas and standards.

## **GVN 8 – Exchange**

### **KEY CONCLUSION**

The core transformation in GVN 8 is the shift in exchange from physical, bank- and organization-centered structures toward digital, platform-mediated and programmatically linked markets. The change is structural because it simultaneously affects payment, marketplaces, trust, taxation, and the responsibility of the consumer. The strongest drivers are global connectivity, interoperable payment rails, AI-assisted coordination and trustworthy digital regulation. The direction is toward exchange that is more continuous, more borderless, and more granularly priced.

### **UNDERLYING LOGIC OF THE GVN**

GVN 8 is organized around enabling the exchange of goods, services and rights easily, safely and efficiently. The current dominant regime is built on physical points of sale, bank-centered payment systems, hierarchical organizations, and control mechanisms anchored in stability. It is underpinned by the value placed on security, auditability, and familiar roles.

The challenger regime is based on e-commerce, global platforms, automation, the sharing economy, cryptocurrencies, and new digital service environments. This suggests that exchange is shifting away from individual organizations toward a structure dominated by protocols, payment layers, and data-driven marketplaces.

### **ANTICIPATED DIRECTION OF TRANSFORMATION**

The anticipated direction is toward lower-friction exchange in which payment, contracting, logistics, and the customer interface merge into a single programmable chain. The main benefits are ease, greater comparability for consumers, and the emergence of new market forms, but also changes in regulation, the tax base, and user responsibility. This suggests that the basic unit of exchange is no longer the individual purchase event, but an increasingly continuous relationship between the user, data, and the service platform.

The interoperability of payment and regulation will determine whether exchange becomes genuinely more open or only more tightly controlled by new platform intermediaries. It remains unclear how much of the traditional retail and banking structure will remain as a durable anchor, even though the pressure for change is clear.

## ESTIMATED PACE OF TRANSFORMATION

- 2018–2026: fast. E-commerce, digital platforms and new forms of payment have already changed exchange rapidly between 2018 and 2026.
- 2026–2045: moderate but accelerating. The next phase depends on how far interoperability in payment, identity and regulation actually extends; if it succeeds, the acceleration could be strong.

## MOST INFLUENTIAL ARTS FOR THIS GVN

- ART 12.095 Interoperable Digital Currency Payment Networks — impact score in GVN 8: 20 — connects payment and settlement across different systems; in this GVN it strengthens digital, continuous, and cross-border exchange.
- ART 01.001 Global Broadband Connectivity — impact score in GVN 8: 20 — builds a near-ubiquitous connectivity layer; in this GVN it strengthens digital, continuous, and cross-border exchange.
- ART 12.096 Machine-Readable Regulation (Rules as Code) — impact score in GVN 8: 5 — turns the interpretation of rules into something that can be implemented programmatically; in this GVN it strengthens digital, continuous, and cross-border exchange.
- ART 03.017 Trustworthy AI Systems — impact score in GVN 8: 10 — makes the use of AI more auditable and institutionally acceptable; in this GVN it strengthens digital, continuous, and cross-border exchange.

## GVN SUMMARY

GVN 8 is strategically important because it determines how value changes hands across other networks. The transformation is already underway and is likely to deepen further. The greatest uncertainty is whether friction in exchange falls for everyone or whether power merely shifts to new digital gatekeepers.

## GVN 9 – Remote Impact

### KEY CONCLUSION

The core transformation in GVN 9 is the erosion of physical presence as a privileged condition for influence, work, interaction and control across many areas. The change is partly discontinuous because the same technical infrastructure can both democratize participation and concentrate influence. The strongest drivers are global connectivity, satellite-based connectivity, immersive interfaces, and robots that extend remote impact into the physical world. The direction is toward a society in which distance is less and less a decisive barrier, while problems of authenticity and control grow.

### UNDERLYING LOGIC OF THE GVN

GVN 9 is organized around enabling influence over other people, spaces and processes from a distance. The current dominant regime rests on physical presence,

organized communication channels, bureaucracy, and the special status of face-to-face influence. Friction related to distance has acted as a constraint on administration, work, and social interaction alike.

The challenger regime is built on global IT platforms, new channels of influence, remotely controlled robots and avatars, machine perception, VR/AR environments, and synthetic media. This suggests that remote impact will not remain a matter of communication only but will increasingly extend into physical environments and decision-making.

## **ANTICIPATED DIRECTION OF TRANSFORMATION**

The anticipated direction is toward a model in which influence, coordination, guidance, oversight, and participation can increasingly take place without a shared location. The main benefits are accessibility, efficiency, and the emergence of new operating models, but the material also highlights misuse, manipulation, and technological unreliability. This suggests that remote impact is becoming a normal societal mode of action rather than an exceptional solution.

Remote impact is likely to deepen quickly where it can be linked to strong authentication, a high-quality sense of presence and reliable remote-action capability. It remains unclear how quickly people and institutions will learn to distinguish authentic, manipulated, and automatically generated forms of remote influence from one another.

## **ESTIMATED PACE OF TRANSFORMATION**

- 2018–2026: fast. The technical basis for remote impact has strengthened rapidly, especially in communication, platforms and hybrid work.
- 2026–2045: fast and potentially discontinuous. If robots, immersion, and synthetic media connect seamlessly to the communications infrastructure, the expansion of remote impact may accelerate strongly by 2045.

## **MOST INFLUENTIAL ARTS FOR THIS GVN**

- ART 01.001 Global Broadband Connectivity — impact score in GVN 9: 20 — builds a near-ubiquitous connectivity layer; in this GVN it strengthens the normalization of remote impact alongside physical presence.
- ART 10.079 Satellite Mega-Constellations & Space Internet — impact score in GVN 9: 10 — extends connectivity, positioning and visibility into areas where terrestrial infrastructure is weak; in this GVN it strengthens the normalization of remote impact alongside physical presence.
- ART 04.022 Immersive Augmented & Virtual Reality — impact score in GVN 9: 10 — brings experiential and simulated environments into everyday activity; in this GVN it strengthens the normalization of remote impact alongside physical presence.

- ART 05.031 Humanoid and General-Purpose Robots — impact score in GVN 9: 20 — brings general-purpose robotics into environments designed for humans; in this GVN it strengthens the normalization of remote impact alongside physical presence.

## **GVN SUMMARY**

GVN 9 is strategically important because it changes the meaning of distance across many other networks. The shift is already visible and may deepen rapidly. The greatest uncertainty concerns whether authenticity, trust and controllability can be preserved when remote impact becomes ubiquitous.

## **GVN 10 – Automation of Work**

### **KEY CONCLUSION**

The core transformation in GVN 10 is the automation of work moving from individual machines toward broad, coordinated, and partly human-independent task networks. The change is structural because it affects the organization of work, the tax base, professional identities, and what is regarded as human work in the first place. The strongest drivers are collaborative multi-agent AI, trustworthy AI, general-purpose robots, edge-based perception, and supportive infrastructure for autonomy. This is one of the fastest and broadest shifts across the whole economy.

### **UNDERLYING LOGIC OF THE GVN**

GVN 10 is organized around producing work outputs efficiently, safely and appropriately. The current dominant regime is based on repetitive automation, human-operated machines, the centrality of human skills, and the view that machines complement rather than broadly replace human labor. The system is sustained by professional identities, the need for control, and fear of autonomous machines.

The challenger regime centers on advanced autonomous machines, AI and machine learning, mobile robotics, 3D printing, sharing logic, and 24/7 service readiness. This suggests that work automation no longer means the mechanization of a single work step, but entire task chains in which humans remain in roles of supervision, exception handling, and goal setting.

### **ANTICIPATED DIRECTION OF TRANSFORMATION**

The anticipated direction is toward production and service environments in which more tasks can be launched, monitored, and corrected programmatically. The main benefits are productivity, availability, and lower costs, but at the same time liability, ethics, and tax-based issues become more acute. This suggests that work automation will spread gradually to almost all environments in which tasks can be described, sensed, and turned into machine decision or execution chains.

The change is likely to accelerate as trustworthy AI and physically general-purpose robotics move closer together. It remains unclear when the adaptation of human trust, responsibility structures and occupational systems will begin to follow technological possibility rather than slow it down.

### **ESTIMATED PACE OF TRANSFORMATION**

- 2018–2026: moderate but accelerating. The basic layers of automation have strengthened quickly, but the broad deployment of human-independent task networks is still incomplete.
- 2026–2045: fast. By 2045, the technological drivers appear mature enough to reshape the structure of work widely, if institutional barriers do not halt the process.

### **MOST INFLUENTIAL ARTS FOR THIS GVN**

- ART 03.019 Collaborative Multi-Agent AI — impact score in GVN 10: 20 — enables coordinated action among many machines, software systems, and actors; in this GVN it strengthens the shift of work toward machine-produced performance.
- ART 03.017 Trustworthy AI Systems — impact score in GVN 10: 20 — makes the use of AI more auditable and institutionally acceptable; in this GVN it strengthens the shift of work toward machine-produced performance.
- ART 05.031 Humanoid and General-Purpose Robots — impact score in GVN 10: 20 — brings general-purpose robotics into environments designed for humans; in this GVN it strengthens the shift of work toward machine-produced performance.
- ART 05.034 Supportive Infrastructure for Autonomy — impact score in GVN 10: 20 — builds the physical and digital support layer required by autonomy; in this GVN it strengthens the shift of work toward machine-produced performance.

### **GVN SUMMARY**

GVN 10 is strategically important because it directly reshapes work, taxation, and skill demand. The change appears to be accelerating and broad-based. The greatest uncertainty is how society handles the transformation of responsibility, livelihood, and the meaning of work.

## **GVN 11 – Work and Income**

### **KEY CONCLUSION**

The core transformation in GVN 11 is the detachment of work, earning, and economic agency from the exclusive model of wage labor and hierarchical organization. The change may be discontinuous because the same technologies that free work from place and institutions can also concentrate market power in new platforms.

The strongest drivers are connectivity, general-purpose robotics, AutoML, trustworthy AI, and digital learning networks. This is not only a labor-market change, but a reorganization of welfare, taxation, and social status.

## **UNDERLYING LOGIC OF THE GVN**

GVN 11 is organized around giving people the possibility to earn a livelihood, save resources, and influence their own well-being and the position of those close to them. The current dominant regime rests on specialized wage labor, large production structures, a strong role for ownership and capital, and the taxation of work. It is underpinned by the value placed on security, stability, hierarchies, and familiar roles.

The challenger regime emphasizes AI and robotization, the platform economy, crowdsourcing, small-scale self-sufficiency, remote work and self-direction. This suggests that the relationship between work and income is fragmenting: some income still arises in organizations, some on platforms, some through self-service and self-provisioning, and some through entirely new digital niches.

## **ANTICIPATED DIRECTION OF TRANSFORMATION**

The anticipated direction is toward a diversification of work in which stable employment does not disappear entirely, but ceases to be the only socially legitimate form of livelihood. The main benefits are more meaningful work, greater self-direction, and lower transaction costs, but at the same time the erosion of the tax base, social-security challenges, and the psychological attachment to wage labor come to the fore. This suggests that the adaptive capacity of institutions is the real bottleneck of the transition.

If tools, connectivity and automated production resources truly democratize, part of the value of work may shift back to small actors and local networks. It remains unclear to what extent platforms, property rights, and algorithmic control capture this potential into a new dependency relationship.

## **ESTIMATED PACE OF TRANSFORMATION**

- 2018–2026: moderate. Remote work, platforms, and AI have already changed forms of earning, but the institutional core of wage labor remains strong.
- 2026–2045: fast and potentially discontinuous. By 2045, the combined effect of automation, the democratization of tools, and learning networks may rapidly alter the relationship between work and income if institutions begin to adapt.

## **MOST INFLUENTIAL ARTS FOR THIS GVN**

- ART 01.001 Global Broadband Connectivity — impact score in GVN 11: 20 — builds a near-ubiquitous connectivity layer; in this GVN it strengthens the dispersion of earning and work into forms beyond wage labor.

- ART 05.031 Humanoid and General-Purpose Robots — impact score in GVN 11: 20 — brings general-purpose robotics into environments designed for humans; in this GVN it strengthens the dispersion of earning and work into forms beyond wage labor.
- ART 03.018 Automated Machine Learning (AutoML) — impact score in GVN 11: 20 — lowers the threshold for using advanced analytics and optimization tools; in this GVN it strengthens the dispersion of earning and work into forms beyond wage labor.
- ART 11.089 Digital Learning Networks and Skill Credentialing — impact score in GVN 11: 10 — turns learning, the collection of evidence and qualifications into portable networks; in this GVN it strengthens the dispersion of earning and work into forms beyond wage labor.

## GVN SUMMARY

GVN 11 is strategically important because it defines the future logic of livelihood, taxation, and social position. The change may accelerate sharply if technological and institutional drivers align at the same time. The greatest uncertainty is whether the outcome is broader agency or a new and even less concealed dependency on platforms.

## GVN 12 – Health Care

### KEY CONCLUSION

The core transformation in GVN 12 is the shift from centralized health care built around population-level standards toward personalized, continuous, and partly user-managed health maintenance. The change is structural, but not necessarily institutionally revolutionary, because old systems will remain in parallel for a long time. The strongest drivers are trustworthy AI, precision medicine, connectivity, edge diagnostics, and an interoperable device ecosystem. The direction is toward health as a service and the continuous management of data flows, rather than the episodic care visit.

### UNDERLYING LOGIC OF THE GVN

GVN 12 is organized around enabling a healthy life for as long as possible and around preventing and treating disease. The current dominant regime rests on centralized and bureaucratic health-care systems, general recommendations, tight professional regulation, and institutional trust. It is underpinned by the values of equality, population health, and controlled pharmaceutical and care chains.

The challenger regime emphasizes personalized medicine, self-diagnostics, wearables, AI, genomics, biohacking, and innovations aimed at extending life. This suggests that health is beginning to split in two: some care remains strongly institutional, but an increasing share of measurement, prevention and choice moves closer to the user.

## ANTICIPATED DIRECTION OF TRANSFORMATION

The anticipated direction is toward a system in which health is produced more continuously through data, analytics and individualized interventions. The main benefits are better targeting, greater individuality, and more anticipatory care, but misinformation, cybersecurity, self-diagnosis errors, and conflicts with professionals also come to the fore. This suggests that the legitimacy of health care will increasingly depend on its ability to combine personalization with reliability.

The change is likely to accelerate where data can be linked to clear benefits without shifting responsibility entirely onto the individual. It remains unclear how much inequality will grow if personalized health solutions are first more accessible to those with greater purchasing power or stronger digital skills.

## ESTIMATED PACE OF TRANSFORMATION

- 2018–2026: moderate but accelerating. Wearables, AI and the use of genomic information have strengthened rapidly, but the basic system remains strongly institutional.
- 2026–2045: fast. By 2045, the combined effect of data, diagnostics and trustworthy AI may shift the center of gravity of health care decisively toward personalized and continuous care.

## MOST INFLUENTIAL ARTS FOR THIS GVN

- ART 09.073 Precision Medicine & Genomic Diagnostics — impact score in GVN 12: 20 — targets diagnostics and treatment to the individual biological profile; in this GVN it strengthens personalized and continuous health management.
- ART 03.017 Trustworthy AI Systems — impact score in GVN 12: 20 — makes the use of AI more auditable and institutionally acceptable; in this GVN it strengthens personalized and continuous health management.
- ART 01.003 Edge AI for Sensor Data — impact score in GVN 12: 10 — brings sensing and decision-making close to the actual situation; in this GVN it strengthens personalized and continuous health management.
- ART 12.091 Universal IoT Interoperability Standards — impact score in GVN 12: 10 — lowers the friction of interoperability across device and system ecosystems; in this GVN it strengthens personalized and continuous health management.

## GVN SUMMARY

GVN 12 is strategically important because it directly affects quality of life, the cost structure of care, and the functional capacity of the population. The change appears accelerating but layered. The greatest uncertainty is how personalization, reliability, and equality can be kept within the same system.

## GVN 13 – Redressing Disabilities

### KEY CONCLUSION

The core transformation in GVN 13 is the shift from a model centered on protection and simple compensation toward an approach that actively expands functional capacity and augments it technologically. The change is structural but uneven, because the integration of assistance, rehabilitation, and autonomy-enhancing technologies is progressing at different speeds. The strongest drivers are advanced prosthetics and exoskeletons, trustworthy AI, edge-based sensor interpretation, robotics, and autonomous mobility. The direction is toward solutions in which barriers are removed both from the environment and from limitations in the user's own functional capacity at the same time.

### UNDERLYING LOGIC OF THE GVN

GVN 13 is organized around correcting or compensating for the harms caused by disability, functional limitations, or reduced capacity. The current dominant regime is based on institutional and home care, simple assistive devices, limited use of new technology, and strong guidance. Behind it are paternalism, protection and basic accessibility solutions.

The challenger regime centers on robotics, AI, artificial organs and implants, advanced assistive devices, personal AI assistants, and community-based forms of support. This suggests that the redressing of disability is shifting from compensation alone toward the active expansion of functional capacity and stronger self-reliance.

### ANTICIPATED DIRECTION OF TRANSFORMATION

The anticipated direction is toward solutions in which physical support, cognitive assistance and environmental intelligence are linked together. The main benefits are greater independence, inclusion, and active aging, but the material also raises concerns on cybersecurity, data security, the risks of experimental solutions, and the challenge of rapid change. This suggests that the technical potential is strong, but the scale of the effects will be determined by acceptability and usability.

Environmental accessibility and personal technology are likely to function as mutually reinforcing layers rather than alternatives. It remains unclear how much advanced solutions can be funded through the public service system and how much of the change will remain market-driven.

### ESTIMATED PACE OF TRANSFORMATION

- 2018–2026: moderate. Assistive technology and AI have developed visibly, but broad transformation of the service structure is still incomplete.
- 2026–2045: moderate but accelerating. By 2045, technological capability may advance greatly, but the scale of the effects will depend on funding, safety and legal acceptability.

## **MOST INFLUENTIAL ARTS FOR THIS GVN**

- ART 04.024 Advanced Prosthetics & Exoskeletons — impact score in GVN 13: 20 — expands physical capacity through advanced assistive devices; in this GVN it strengthens the technological expansion and compensation of functional capacity.
- ART 03.017 Trustworthy AI Systems — impact score in GVN 13: 10 — makes the use of AI more auditable and institutionally acceptable; in this GVN it strengthens the technological expansion and compensation of functional capacity.
- ART 05.029 Self-Driving Vehicles — impact score in GVN 13: 10 — shifts decision and control capacity from the human driver to the system; in this GVN it strengthens the technological expansion and compensation of functional capacity.
- ART 01.001 Global Broadband Connectivity — impact score in GVN 13: 10 — builds a near-ubiquitous connectivity layer; in this GVN it strengthens the technological expansion and compensation of functional capacity.

## **GVN SUMMARY**

GVN 13 is strategically important because it directly concerns autonomy, participation and equality. The change appears realistic but layered. The greatest uncertainty is whether advanced solutions become broadly available or remain the benefit of a narrow user group.

# **GVN 14 – Acquiring Information**

## **KEY CONCLUSION**

The core transformation in GVN 14 is the shift in information acquisition from authorized sources and publishing organizations toward a decentralized, machine-mediated environment exposed to an authenticity crisis. The change is rapid and partly discontinuous because the availability, interpretation, and verifiability of information are changing at the same time. The strongest drivers are communications infrastructure, content-authenticity solutions, trustworthy AI, edge-based sensing, and satellite-based visibility. The direction is toward an information environment in which the volume of information grows, but the legitimacy of information becomes a more contested question.

## **UNDERLYING LOGIC OF THE GVN**

GVN 14 is organized around enabling the acquisition of information about events, conditions, and meanings in the world. The current dominant regime rests on organized information gathering, media publishing, limited observation, and officially certified sources. It is underpinned by belief in authorities, dependence on established sources, and the entertainmentization of information.

The challenger regime emphasizes digital platforms, search engines, AI, more advanced measuring devices, crowdsourcing, and machine interpretation. This suggests that information acquisition is increasingly becoming a question of who gets to produce observations, how they are filtered, and under what conditions they are regarded as authentic.

## **ANTICIPATED DIRECTION OF TRANSFORMATION**

The anticipated direction is toward near-continuous information acquisition in which the user can receive both primary data and preinterpreted views of the same issue. The main benefits are broader availability and stronger local usefulness, but bubbles, external interference, the difficulty of interpretation, and fake sources are also brought forward strongly. This suggests that competitive advantage in information acquisition is shifting increasingly toward verifiability and the quality of interpretation.

Greater technical visibility does not automatically produce greater shared understanding. On the contrary, the more data and interpretation machines are provided, the more important content authenticity, source comparison, and trustworthy AI become. It remains unclear what new institutional balance will emerge between legacy media, platforms and users.

## **ESTIMATED PACE OF TRANSFORMATION**

- 2018–2026: fast. The technical and organizational basis of information acquisition has already changed extremely quickly between 2018 and 2026.
- 2026–2045: fast and potentially discontinuous. By 2045, the combination of authenticity infrastructure, AI interpretation, and distributed sensing may alter the entire logic of information acquisition at once across multiple sectors.

## **MOST INFLUENTIAL ARTS FOR THIS GVN**

- ART 01.001 Global Broadband Connectivity — impact score in GVN 14: 20 — builds a near-ubiquitous connectivity layer; in this GVN it strengthens the decentralization of information acquisition and the new need for verifiability.
- ART 12.098 Content Authenticity Infrastructure — impact score in GVN 14: 20 — makes the origin and integrity of content more verifiable; in this GVN it strengthens the decentralization of information acquisition and the new need for verifiability.
- ART 03.017 Trustworthy AI Systems — impact score in GVN 14: 10 — makes the use of AI more auditable and institutionally acceptable; in this GVN it strengthens the decentralization of information acquisition and the new need for verifiability.
- ART 01.003 Edge AI for Sensor Data — impact score in GVN 14: 10 — brings sensing and decision-making close to the actual situation; in this GVN it strengthens the decentralization of information acquisition and the new need for verifiability.

## **GVN SUMMARY**

GVN 14 is strategically important because it directly affects what is regarded as true and usable information. The change appears extremely fast. The greatest uncertainty is whether abundant information produces more shared visibility or a deeper crisis of trust.

## **GVN 15 – Proficiency and its Proof**

### **KEY CONCLUSION**

The core transformation in GVN 15 is the shift from degree- and institution-centered validation of competence toward continuous, evidence-based, and technologically supported credential building. The change is structural because it simultaneously affects learning, labor markets, certification, and the role of educational organizations. The strongest drivers are digital learning networks, trustworthy AI, immersive training, content authenticity, and the portability of personal data. The direction is toward competence that is increasingly demonstrated through practical evidence rather than through a single formal gatekeeper.

### **UNDERLYING LOGIC OF THE GVN**

GVN 15 is organized around enabling the acquisition of proficiency and its credible verification. The current dominant regime rests on traditional educational institutions, official assessment, siloed teaching, and recognition centered on titles and degrees. It is underpinned by the strong role of authorities and institutional quality assurance.

The challenger regime emphasizes online learning, simulations, gamification, VR/AR, competence-based credentials, and learning to learn. This suggests that the value of competence is shifting increasingly toward performance, evidence, and continuous updating rather than formal educational pathways alone.

### **ANTICIPATED DIRECTION OF TRANSFORMATION**

The anticipated direction is toward a system in which learning is distributed across many environments while verification simultaneously becomes technically more precise. The main benefits are more direct feedback, stronger motivation, and more individualized progression, but the material also raises the readiness of teachers, quality assurance, and unequal access. This suggests that the transition succeeds only when new learning modes and credible verification develop together.

The relationship between labor markets and education is likely to change substantially. If competence can be demonstrated more precisely, the significance of the traditional degree monopoly also declines. It remains unclear how far employers, authorities, and professional communities are willing to give up older marks of quality.

## ESTIMATED PACE OF TRANSFORMATION

- 2018–2026: moderate but accelerating. Online learning, simulations, and the use of competence data have strengthened quickly, but the formal logic of degrees remains strong.
- 2026–2045: fast. By 2045, evidence-based credentialing and digital learning may rapidly reshape the logic of qualification if employers and institutions begin to trust new forms of proof.

## MOST INFLUENTIAL ARTS FOR THIS GVN

- ART 11.089 Digital Learning Networks and Skill Credentialing — impact score in GVN 15: 20 — links learning, evidence collection, and qualifications into portable networks; in this GVN it strengthens evidence-based and continuously updated validation of competence.
- ART 04.022 Immersive Augmented & Virtual Reality — impact score in GVN 15: 10 — brings experiential and simulated environments into everyday activity; in this GVN it strengthens evidence-based and continuously updated validation of competence.
- ART 12.098 Content Authenticity Infrastructure — impact score in GVN 15: 10 — makes the origin and integrity of content more verifiable; in this GVN it strengthens evidence-based and continuously updated validation of competence.
- ART 12.094 Personal Data Portability & Trust Frameworks — impact score in GVN 15: 10 — gives the user a portable way to manage identity, rights and profile data; in this GVN it strengthens evidence-based and continuously updated validation of competence.

## GVN SUMMARY

GVN 15 is strategically important because it affects how capability is recognized and how people gain access to new roles. The change appears to be accelerating, but it depends on institutional acceptance. The greatest uncertainty is whether a genuinely open competence system emerges or a new certification monopoly.

## GVN 16 – Producing Experiences

### KEY CONCLUSION

The core transformation in GVN 16 is the shift from passive consumption toward participatory, immersive, and continuously networked experiences. The change is partly discontinuous because technology simultaneously changes content production, distribution, forms of participation, and the economic logic of experiences. The strongest drivers are global connectivity, XR, AI's ability to interpret human intent, and edge-based interpretation of sensory data. The direction is toward experiences that are less tied to place, more co-produced, and more precisely personalized.

## UNDERLYING LOGIC OF THE GVN

GVN 16 is organized around producing experiences, art, entertainment, and meaningful forms of participation. The current dominant regime rests on traditional art and entertainment forms, the producer–consumer relationship, institutions, and the authenticity of physical presence. It is underpinned by passive consumption, the preservation of tradition, and established production and distribution channels.

The challenger regime emphasizes digitalization, VR/AR, AI, robotics, interactivity and the democratization of experiences. This suggests that experience production is shifting away from the control of a few institutions toward an environment in which audiences, technology and distribution platforms shape content together.

## ANTICIPATED DIRECTION OF TRANSFORMATION

The anticipated direction is toward experiences that are at once personalized, shared and multisensory. The main benefits are greater creativity, stronger sociality, and new forms of experience with ethical or mission-driven emphasis, but addiction, manipulation and social alienation are also raised as risks. This suggests that competitive advantage in the experience economy is shifting from content alone toward the ability to manage the form of participation and the intensity of the social experience.

Experience production is one of the GVNs in which technological change quickly becomes visible in everyday practice. It remains unclear how durable the value of authentic physical presence will be and to what extent institutions can preserve their position in the new experience economy.

## ESTIMATED PACE OF TRANSFORMATION

- 2018–2026: fast. Connectivity, platforms and digital participation have already changed the production of experiences rapidly between 2018 and 2026.
- 2026–2045: fast and potentially discontinuous. By 2045, the combination of XR, AI and intent interpretation may alter the entire logic of the experience economy very quickly.

## MOST INFLUENTIAL ARTS FOR THIS GVN

- ART 01.001 Global Broadband Connectivity — impact score in GVN 16: 20 — builds a near-ubiquitous connectivity layer; in this GVN it strengthens immersive, participatory, and personalized experiences.
- ART 04.022 Immersive Augmented & Virtual Reality — impact score in GVN 16: 20 — brings experiential and simulated environments into everyday activity; in this GVN it strengthens immersive, participatory, and personalized experiences.
- ART 04.026 AI Understanding of Human Intent & Context — impact score in GVN 16: 20 — interprets human intent, context and needs more effectively than before; in this GVN it strengthens immersive, participatory, and personalized experiences.

- ART 01.003 Edge AI for Sensor Data — impact score in GVN 16: 10 — brings sensing and decision-making close to the actual situation; in this GVN it strengthens immersive, participatory, and personalized experiences.

## **GVN SUMMARY**

GVN 16 is strategically important because it is tied to culture, social relations and the production of meaning. The change appears fast and self-reinforcing. The greatest uncertainty is whether the new experience infrastructure expands participation or increases the risks of manipulation and dependency.

# **GVN 17 – Safety and Security**

## **KEY CONCLUSION**

The core transformation in GVN 17 is the shift from a centralized, reactive and authority-driven safety model toward decentralized, anticipatory, and data-driven production of safety and security. The change is structural, but it contains a strong tension between safety, privacy, and trust. The strongest drivers are trustworthy AI, edge-based sensing, and interoperable IoT standards, supported by connectivity and multi-actor coordination. The direction is toward safety produced as a continuous interaction among the environment, the user and systems.

## **UNDERLYING LOGIC OF THE GVN**

GVN 17 is organized around protecting people, environments, and systems from threats, risks, and harm. The current dominant regime rests on centralized authorities, periodic inspections, reactive measures, and hierarchical control. It is underpinned by normativity, trust in institutions, and the expectation that society produces safety mainly from the top down.

The challenger regime emphasizes decentralized safety solutions, advanced technologies, personal diagnostics, crowdsourcing, and the growing risk awareness of individuals. This suggests that safety is becoming a continuously measurable and locally produced characteristic rather than merely an institutional service.

## **ANTICIPATED DIRECTION OF TRANSFORMATION**

The anticipated direction is toward a system in which hazard detection, interpretation, and first response move partly closer to the user, devices, and the network edge. The main benefits are anticipation, participation, and individualized preparedness, but privacy issues, the erosion of trust, and the risk of shifting too much responsibility onto the individual are also highlighted. This suggests that improved safety may go hand in hand with a new layer of surveillance.

The legitimacy of the safety system is likely to depend increasingly on whether data-driven approaches can be made transparent and proportionate. It remains unclear how far people will accept continuous monitoring in exchange for a stronger sense of safety.

## ESTIMATED PACE OF TRANSFORMATION

- 2018–2026: moderate. The technological drivers have strengthened clearly, but in the logic of the material, the institutional structure of safety changes more slowly than the technical layer.
- 2026–2045: moderate but accelerating. By 2045, anticipatory and networked safety may strengthen significantly if interoperability and trustworthy AI mature sufficiently.

## MOST INFLUENTIAL ARTS FOR THIS GVN

- ART 03.017 Trustworthy AI Systems — impact score in GVN 17: 20 — makes the use of AI more auditable and institutionally acceptable; in this GVN it strengthens anticipatory and decentralized safety.
- ART 01.003 Edge AI for Sensor Data — impact score in GVN 17: 20 — brings sensing and decision-making close to the actual situation; in this GVN it strengthens anticipatory and decentralized safety.
- ART 12.091 Universal IoT Interoperability Standards — impact score in GVN 17: 20 — lowers the friction of interoperability across device and system ecosystems; in this GVN it strengthens anticipatory and decentralized safety.
- ART 03.019 Collaborative Multi-Agent AI — impact score in GVN 17: 10 — enables coordinated action among many machines, software systems and actors; in this GVN it strengthens anticipatory and decentralized safety.

## GVN SUMMARY

GVN 17 is strategically important because it defines the basis of risk management across many other networks. The change appears medium-paced but steadily strengthening. The greatest uncertainty is the point at which anticipation begins to resemble continuous control and starts to erode trust.

# GVN 18 – Collaboration and Trust

## KEY CONCLUSION

The core transformation in GVN 18 is the shift of trust from personal relationships, hierarchies, and national institutions toward networked, transparent, and technically mediated trust mechanisms. The change is structural, but its success depends on whether the new trust is produced in a genuinely open way or merely through new kinds of gatekeepers. The strongest drivers are global connectivity, decentralized trust networks, trustworthy AI, privacy-preserving learning, and machine-readable regulation. The direction is toward cooperation that can be built more broadly than before without a pre-existing institutional bond.

## UNDERLYING LOGIC OF THE GVN

GVN 18 is organized around enabling cooperation and the building of trust between individuals, communities, and organizations. The current dominant regime is based

on hierarchical trust, cultural norms, public oversight, and the legal system. In addition, national boundaries and the protection of privacy have been key conditions of trust.

The challenger regime emphasizes digital platforms, peer-trust mechanisms, reputation, transparency, blockchain, crowdfunding, and crowdsourcing. This suggests that trust is increasingly becoming a verifiable, measurable, and portable property rather than something grounded only in institutional membership.

## **ANTICIPATED DIRECTION OF TRANSFORMATION**

The anticipated direction is toward a system in which cooperation can be launched among a wider range of actors more quickly than before, provided that identity, data rights, reputation, and the interpretation of rules are interoperable. The main benefits are openness, stronger community, and greater globality, but fraud, regulatory conflicts, and the slow pace of trust-building are also highlighted. This suggests that technical infrastructure can reduce friction, but cannot remove the social cost of building trust.

New trust mechanisms may also change how power is distributed: who can prove, verify, certify, and regulate the terms of cooperation. It remains unclear whether genuinely decentralized trust systems will emerge or whether much of the new trust infrastructure will end up under the control of a few platforms.

## **ESTIMATED PACE OF TRANSFORMATION**

- 2018–2026: moderate. Digital solutions for collaboration and trust have strengthened, but institutional trust has not quickly lost its position.
- 2026–2045: moderate but accelerating. By 2045, the combined effect of data rights, decentralized verification and machine-readable regulation may accelerate the shift clearly.

## **MOST INFLUENTIAL ARTS FOR THIS GVN**

- ART 01.001 Global Broadband Connectivity — impact score in GVN 18: 20 — builds a near-ubiquitous connectivity layer; in this GVN it strengthens networked and technically verifiable trust-building.
- ART 11.083 Decentralized Trust Networks (Web3 & Blockchain) — impact score in GVN 18: 20 — creates technical mechanisms for decentralized verification and transaction trust; in this GVN it strengthens networked and technically verifiable trust-building.
- ART 03.017 Trustworthy AI Systems — impact score in GVN 18: 10 — makes the use of AI more auditable and institutionally acceptable; in this GVN it strengthens networked and technically verifiable trust-building.
- ART 12.096 Machine-Readable Regulation (Rules as Code) — impact score in GVN 18: 10 — turns the interpretation of rules into something that can be implemented programmatically; in this GVN it strengthens networked and technically verifiable trust-building.

## **GVN SUMMARY**

GVN 18 is strategically important because many other networks do not scale without functional trust. The change appears credible but socially demanding. The greatest uncertainty is whether the new trust infrastructure replaces the old one or is built on top of it as a new layer of control.

## **GVN 19 – Existential Meaning**

### **KEY CONCLUSION**

The core transformation in GVN 19 is the shift in the sources of meaning from work, status, and local peer groups toward networks, experiences, communities, and new technological forms of self-expression. The change is slower and more cultural than in many other GVNs, but its effects may be deep. The strongest drivers are connectivity, immersive experiences, trustworthy AI, general-purpose robots, and portable identity. The direction is toward a situation in which meaning is less and less built around a single assumed life path.

### **UNDERLYING LOGIC OF THE GVN**

GVN 19 is organized around giving people the experience that life is purposeful, valuable, and socially recognized. The current dominant regime rests on identity built around work and profession, hierarchical divisions of labor, status competition, and traditional forms of voluntary work. Behind it are the desire for stability, the need for acceptance and fear of change.

The challenger regime emphasizes digitalization, robotization, the gamification of work, local and online communities, VR/AR, and global sharing platforms. This suggests that the production of meaning is gradually detaching from an exclusive hierarchy of work and status and spreading across multiple parallel communities and experiences.

### **ANTICIPATED DIRECTION OF TRANSFORMATION**

The anticipated direction is toward a fragmented but more diverse environment of meaning. The main benefits are new forms of self-expression, global participation, and new communities, but the material also highlights difficult transitions, unrealistic expectations, and the risk of negative influences. This suggests that the new infrastructure of meaning may increase agency, but may also expose people to more unstable comparison and identity pressure than before.

The shift is likely to accelerate if work is automated and experiential and community-based alternatives gain greater cultural legitimacy. It remains unclear whether a new stable structure of meaning will emerge or whether the outcome will be continuous competition for attention, participation and visibility.

## ESTIMATED PACE OF TRANSFORMATION

- 2018–2026: slow but strengthening. In the logic of the material, cultural change proceeds more slowly than technical change, even though platforms and networks have already changed the sources of meaning.
- 2026–2045: moderate. By 2045, automation, networked communities and immersive experiences may reinforce the shift significantly, but cultural adoption is likely to remain relatively slow.

## MOST INFLUENTIAL ARTS FOR THIS GVN

- ART 04.022 Immersive Augmented & Virtual Reality — impact score in GVN 19: 20 — brings experiential and simulated environments into everyday activity; in this GVN it strengthens the shift of meaning toward networks, experiences, and self-expression.
- ART 01.001 Global Broadband Connectivity — impact score in GVN 19: 20 — builds a near-ubiquitous connectivity layer; in this GVN it strengthens the shift of meaning toward networks, experiences, and self-expression.
- ART 12.094 Personal Data Portability & Trust Frameworks — impact score in GVN 19: 10 — gives the user a portable way to manage identity, rights and profile data; in this GVN it strengthens the shift of meaning toward networks, experiences, and self-expression.
- ART 05.031 Humanoid and General-Purpose Robots — impact score in GVN 19: 10 — brings general-purpose robotics into environments designed for humans; in this GVN it strengthens the shift of meaning toward networks, experiences, and self-expression.

## GVN SUMMARY

GVN 19 is strategically important because it concerns life direction, identity, and social recognition. The change appears slow but far-reaching. The greatest uncertainty is whether the old structure of meaning is sustainably replaced or merely dispersed without a new shared foundation.

## GVN 20 – Power Structures

### KEY CONCLUSION

The core transformation in GVN 20 is the shift of power from hierarchical structures tied to geography and organizational position toward networks, protocols, comparable services and partly programmatically enforced governance. The change is clearly structural and may be discontinuous in some areas, because power can move quickly to whoever controls the coding and implementation of rules. The strongest drivers are trustworthy AI, rules as code, platform interoperability and decentralized governance. The direction is toward governance in which power does not disappear, but changes form.

## UNDERLYING LOGIC OF THE GVN

GVN 20 is organized around optimizing shared decision-making in organizations and society. The current dominant regime is built on hierarchical organizations, geographically based public authority, the structural influence of elites, and a broad machinery of legislation and oversight. Behind it are conservatism, traditional decision-making, and an emphasis on stability.

The challenger regime emphasizes digitalization, automation, decentralized and subject-based governance, platform communities, a new boundary between markets and hierarchies, and the use of AI and crowdsourcing. This suggests that the core of power is shifting toward the ability to define rule interfaces, comparability, and verifiable execution.

## ANTICIPATED DIRECTION OF TRANSFORMATION

The anticipated direction is toward governance in which rules can be published, compared, simulated, and enforced more dynamically than before. The main benefits are better decision quality, subsidiarity, democratization, and more flexible control, but the material also highlights costs, complexity, inequality, and resistance from administrative tradition. This suggests that the decentralization of power does not automatically mean an equalization of power.

In this GVN in particular, the compatibility of technology and institutions will decide everything. If regulation, trust, and algorithmic enforcement can be connected credibly, change may accelerate quickly. It remains unclear whether the outcome will be more open governance models or new kinds of technocratic gatekeepers.

## ESTIMATED PACE OF TRANSFORMATION

- 2018–2026: slow but strengthening. In the logic of the material, power structures change slowly, even though digitalization has already opened up new alternatives and new pressures.
- 2026–2045: moderate but accelerating. By 2045, the machine-readability of rules, decentralized governance and platform models may speed up the change if legitimacy can be preserved.

## MOST INFLUENTIAL ARTS FOR THIS GVN

- ART 03.017 Trustworthy AI Systems — impact score in GVN 20: 20 — makes the use of AI more auditable and institutionally acceptable; in this GVN it strengthens the shift of power and governance from hierarchies toward code and networks.
- ART 12.096 Machine-Readable Regulation (Rules as Code) — impact score in GVN 20: 20 — turns the interpretation of rules into something that can be implemented programmatically; in this GVN it strengthens the shift of power and governance from hierarchies toward code and networks.

- ART 11.084 Platform Cooperatives & Fair Work — impact score in GVN 20: 20 — offers an alternative to investor-driven platforms as community-owned networks; in this GVN it strengthens the shift of power and governance from hierarchies toward code and networks.
- ART 11.088 Scalable Decentralized Governance — impact score in GVN 20: 20 — makes decentralized decision-making by large groups more feasible; in this GVN it strengthens the shift of power and governance from hierarchies toward code and networks.

## GVN SUMMARY

GVN 20 is strategically important because it defines the rules of the game for other networks. The change will probably advance slowly at first, but may accelerate as new forms of governance prove their practicality. The greatest uncertainty is whether power actually broadens or only shifts into new technological forms of mediation.

# Summary of results 2: 12 technology groups, 100 anticipated radical technologies

This is a summary of the anticipated radical technology breakthroughs. The ARTs form twelve broad technology groups whose expected development is introduced here. Each group is complemented with a list of ARTs belonging to it.

The maturity levels mentioned in the ART lists vary in the range from 1 to 7 (for full maturity criteria, see Attachment 6):

1. Scientific principle has been theoretically proven
2. Scientific principle has been measured in laboratory
3. Functional laboratory prototype exists
4. Proof-of-Concept: Prototype does useful work
5. Competing production prototypes are being developed
6. Products are delivered to customers
7. Competing products are increasingly delivered to customers

The ART lists also mention total impact score for each ART. This anticipated impact varies from 16 (ART 10.081: Closed-loop life support systems) to 1440 (ART 01.001: Global broadband connectivity). For complete ranking of all 100 ARTs, see Attachment 1. ART total impact scores are calculated by summing up an ARTs potential

maximum impact in each GVN by year 2045 and multiplying it by the maturity. Detailed principles on how ART impact in a GVN is evaluated, see Attachment 6.

All the 100 ARTs are described in detail in Attachment 2 in terms of how each ART is anticipated to solve a certain technological bottleneck and what is its potential and maturity. Also, the evidence of each ART's current development status is presented. Further, the impact of each ART within each GVN is analysed in Attachment 3. In this summary, the development is described jointly for each different technology group. This summary was created by using the RTI-GPT.

## Group 1 – Sensing, Measurement & Connectivity

### KEY CONCLUSION

Group 1 brings together technologies that turn sensing, measurement, and connectivity into infrastructural capabilities rather than isolated devices. The group matters because almost all later automation, AI, and platform solutions depend on data being generated reliably, moving to the right place, and remaining usable even under disruption. The group is mostly enabling, but already directly transformative in some areas: broadband connectivity, edge computing, and privacy-preserving sensing are moving from early adoption into broader basic infrastructure. At the same time, some subtracks, such as integrated sensing and communication (ISAC) and parts of quantum sensing, are still clearly in the development phase.

### SIGNIFICANCE OF THE TECHNOLOGY AREA

The common denominator of the group is turning the physical world into something that can be continuously measured, interpreted, and networked. It addresses bottlenecks related to slow observation, breaks in data transfer, the limits of centralized computing, and the fact that in many environments, signals are too weak, noisy, or delayed for safe automation. When sensing, communication, and local decision-making are combined, they create the basis for real-time coordination, remote operation, safety, and operational reliability.

The strongest impact appears where large numbers of distributed objects must be kept visible and controllable at the same time: transport, logistics, energy, the built environment, remote operations, and automated services. The group also determines how much power shifts toward networks, sensors, and the actors that control them. Its significance is therefore not only technical but institutional: it affects what can be monitored, verified, optimized and automated, and on what terms.

### DEVELOPMENT OUTLOOK

The most mature subtracks are currently global broadband connectivity, edge AI for sensor data, and privacy-preserving sensing. These already have functioning services, clear commercial use cases and multiple investing actors. Quantum and high-precision sensing, as well as quantum-resilient communication, are beyond

pure research, but adoption is still selective. Integrated sensing and communication appears promising, but it is still more of an emerging architectural direction than a mature market.

The next phase is likely to arise not from a single breakthrough but from layering: connectivity, sensors, local AI, security and privacy gradually merging into a single operational infrastructure. This also increases dependence on telecom networks, specialized chips, standards and cybersecurity. What remains unclear is which actors will ultimately control this infrastructure layer, how quickly costs will fall and to what extent regulation begins to limit continuous sensing in public environments.

## **ARTS IN THE GROUP**

- ART 01.001 Global Broadband Connectivity — maturity: 6 — total impact score: 1440
- ART 01.002 Ultra-Low Latency Networks — maturity: 5 — total impact score: 505
- ART 01.003 Edge AI for Sensor Data — maturity: 6 — total impact score: 966
- ART 01.004 Quantum & High-Precision Sensing — maturity: 5 — total impact score: 240
- ART 01.005 Micro/Nano Sensor Networks — maturity: 5 — total impact score: 480
- ART 01.006 Privacy-Preserving Pervasive Sensing — maturity: 6 — total impact score: 696
- ART 01.007 Quantum-Resilient and Secure Communication Networks — maturity: 5 — total impact score: 345
- ART 01.008 Integrated Sensing and Communication (ISAC) — maturity: 4 — total impact score: 336

## **GROUP SUMMARY**

The strength of Group 1 lies in providing an operational layer of sensing and connectivity for almost all other technology groups. The greatest uncertainties concern security, privacy, energy efficiency and whether the resulting infrastructure model remains open or becomes highly concentrated. Strategically, the group is important precisely because it often remains invisible to the end user, yet it defines the practical scope within which automation, remote operation and data-driven services can function at all.

## Group 2 – Computing Hardware & Non-Von-Neumann Paradigms

### KEY CONCLUSION

Group 2 brings together technologies that reshape the physical basis of computing: new transistors, memory, photonics, quantum computing, and memory-centric paradigms. The group is highly significant because it affects the energy, speed, and cost at which later AI, sensing, and simulation systems can operate. It is above all enabling rather than already widely and directly transformative. At the same time, it is internally uneven: some solutions are approaching commercial use, while others are still in the research and prototype phase.

### SIGNIFICANCE OF THE TECHNOLOGY AREA

The common denominator of the group is the attempt to break through the limits of the current computing architecture. It addresses bottlenecks related to the energy cost of moving data, the slowing of transistor scaling, thermal load, latency in memory hierarchies, and the fact that many future applications require more computation closer to the sensor and with far smaller power budgets than current platforms allow.

The strongest impact is indirect: the group does not usually transform an industry on its own, but it changes the economic and technical feasibility of other technologies. If computing becomes substantially more energy-efficient, denser or more distributed, the effects appear in edge computing, digital twins, autonomy, photonic information processing, and sensor networks. Its strategic importance is therefore greater than its immediate visibility in the market.

### DEVELOPMENT OUTLOOK

The most mature subtracks are compute-in-memory and neuromorphic chips, next-generation memory and storage, and early specialized uses of photonic computing. These already have working prototypes, some delivered products or clear industrial development paths. New transistor materials and molecular computing are clearly in earlier development phase: their principles and laboratory-scale implementations have been demonstrated, but industrial scale, reliability and the software ecosystem remain open questions.

The group is likely to advance asymmetrically. Instead of one unified new computing paradigm, the market will probably see several parallel specialized solutions: in-memory computing for certain AI workloads, photonics for bandwidth-intensive tasks, new memory technologies between storage and fast cache, and quantum computing for limited optimization and simulation problems. What remains unclear is when these become an invisible new baseline for users, or how quickly they displace the currently dominating CMOS-based solutions at scale.

## ARTS IN THE GROUP

- ART 02.009 Compute-in-Memory & Neuromorphic Chips — maturity: 5  
— total impact score: 405
- ART 02.010 Novel transistor technologies and materials beyond silicon CMOS — maturity: 3 — total impact score: 144
- ART 02.011 Quantum Computing Platforms — maturity: 5  
— total impact score: 170
- ART 02.012 Photonic and Optical Computing — maturity: 5  
— total impact score: 200
- ART 02.013 Next-Gen Memory & Storage — maturity: 5  
— total impact score: 240
- ART 02.014 Molecular Computing — maturity: 3 — total impact score: 18

## GROUP SUMMARY

The strength of Group 2 lies in its potential to remove the energy, thermal and latency bottlenecks that many other radical technologies run into. The greatest uncertainties concern manufacturability, software, standardization, and which sub-tracks will find a sufficiently large market. Strategically, the group matters because it will determine the long-term performance and cost structure of the entire digital infrastructure.

## Group 3 – Artificial Intelligence & Learning Systems

### KEY CONCLUSION

Group 3 describes the evolution of AI toward more coordinated, reliable, and autonomous operation. The group is important because it no longer concerns only the accuracy of individual models, but also how machine learning can be linked to decision-making, collaboration, privacy, automation, and scientific discovery. Some parts of the group are already directly transformative: multi-agent AI, federated learning, AutoML and trustworthy AI are moving into practical deployment. Causal reasoning and autonomous scientific discovery are still more emerging capabilities than established infrastructure.

### SIGNIFICANCE OF THE TECHNOLOGY AREA

The common denominator of the group is the shift of AI from pattern recognition toward more systematic collaboration, causal understanding, safe deployment, and scalable learning. It addresses bottlenecks related to fragmented data, the difficulty of maintaining models, reliability, coordination, and the fact that complex environments require many agents acting together rather than predictions from one model alone.

The strongest impact appears where decisions must be made quickly, in distributed form and with justification: network control, autonomy, logistics, production, platform economies, and research. At the same time, the group changes organizational power relations by moving more judgment and optimization into software stacks, data integration, and safety assurance. This makes it a change in operating logic, not just a group of tools.

## DEVELOPMENT OUTLOOK

The most mature subtracks are collaborative multi-agent AI, federated and privacy-preserving learning, AutoML, and several trustworthy AI practices. These already have production use, functioning software libraries, pilots or growing standardization. Causal learning and reasoning is clearly useful, but still only mid-stage in terms of the full promise. AI-driven autonomous scientific discovery has moved well beyond prototypes, toward concrete use cases, but not yet into broad research infrastructure.

The next phase is likely to develop along two converging directions. The first is operational: multiple agents, automated model building, and privacy-compatible learning become part of everyday processes. The second is epistemic: models must produce results that are better justified, auditable, and resistant to intervention errors. What remains unclear is when reliability and causal requirements become real market thresholds, or to what extent autonomous AI-driven discovery begins to replace human-led research processes.

## ARTS IN THE GROUP

- ART 03.015 Causal Learning & Reasoning — maturity: 4 — total impact score: 512
- ART 03.016 Federated & Privacy-Preserving Learning — maturity: 6 — total impact score: 726
- ART 03.017 Trustworthy AI Systems — maturity: 5 — total impact score: 1065
- ART 03.018 Automated Machine Learning (AutoML) — maturity: 6 — total impact score: 636
- ART 03.019 Collaborative Multi-Agent AI — maturity: 6 — total impact score: 1080
- ART 03.020 Quantum-Accelerated AI Systems — maturity: 5 — total impact score: 120
- ART 03.021 AI-Driven Autonomous Scientific Discovery — maturity: 5 — total impact score: 330

## GROUP SUMMARY

The strength of Group 3 lies in its ability to turn AI from an isolated analytics function into a layer for coordinating and governing action. The greatest uncertainties concern explainability, safety, data governance, and how much decision-making

organizations are willing to transfer to agent systems. Strategically, the group is important because it affects productivity, risk management, and the governing logic of the digital economy at the same time.

## **Group 4 – Human-Machine Interaction & Augmentation**

### **KEY CONCLUSION**

Group 4 brings together technologies that reshape the interface between humans and systems. Its significance lies in making digital environments more immediate, natural and individualized, but also in deepening surveillance, interpretation, and dependence on neuro- or behavioral data. The group is highly heterogeneous: XR and advanced prosthetics are already relatively mature, while brain-to-brain interfaces and memory prostheses are still at a much earlier development stage. Overall, the group is more enabling and human-centered than directly transformative at the level of whole systems.

### **SIGNIFICANCE OF THE TECHNOLOGY AREA**

The common denominator of the group is the deepening of the interface. Its technologies aim to reduce friction between human perception, intention and movement and the digital system. They address bottlenecks related to remote or clumsy interaction, difficult-to-interpret context, limits in physical capability, and the fact that today's keyboard, screen, and touch paradigms are no longer sufficient for all use cases.

The strongest impact appears in training, remote operation, healthcare, industrial support, accessibility, and new consumer interfaces. At the same time, the group changes what can be inferred or measured about a person during use: intent, attention, memory function, and neural response can become part of the system's input. This creates both major potential and significant ethical and regulatory tensions.

### **DEVELOPMENT OUTLOOK**

The most mature subtracks are immersive AR/VR and advanced prosthetics and exoskeletons. These already have products, competition, and growing adoption. Brain-computer interfaces have moved from the laboratory stage to clinical or early commercial paths, but the field remains unfinished. AI understanding of human intent and context is important, but still mid-stage because deployment requires both technical reliability and social acceptability.

The greatest impact may not come from a single breakthrough product, but from the convergence of multiple interface technologies. XR, intent interpretation, haptic systems, and neural interfaces may together shift many activities toward more natural control and more individualized support. What remains unclear is long-term acceptance, price development, and the extent to which consumers accept the use of deep behavioral and neural data in everyday interfaces.

## ARTS IN THE GROUP

- ART 04.022 Immersive Augmented & Virtual Reality — maturity: 6  
— total impact score: 852
- ART 04.023 Brain-Computer Interfaces (BCI) — maturity: 5  
— total impact score: 275
- ART 04.024 Advanced Prosthetics & Exoskeletons — maturity: 6  
— total impact score: 420
- ART 04.025 Haptic and Multi-Sensory Feedback Systems — maturity: 4  
— total impact score: 264
- ART 04.026 AI Understanding of Human Intent & Context — maturity: 4  
— total impact score: 640
- ART 04.027 Brain-to-Brain Interfaces — maturity: 3 — total impact score: 57
- ART 04.028 Memory Prostheses — maturity: 4 — total impact score: 116

## GROUP SUMMARY

The strength of Group 4 lies in its ability to improve usability, accessibility and human capability in situations where current interfaces are too clumsy. The greatest uncertainties concern safety, data protection, clinical evidence and social acceptance. Strategically, the group matters because the interface often determines whether a technology remains a niche solution or becomes part of everyday life.

## Group 5 – Robotics & Physical Autonomy

### KEY CONCLUSION

Group 5 brings together the technologies of physical autonomy: self-driving vehicles, general-purpose robots, autonomous aerial and aquatic systems, and the environments that support them. This is one of the clearest directly transformative groups because it affects the division of labor, safety, the use of space, and the way services are delivered. The group is nevertheless internally uneven: self-driving vehicles and some autonomous robotic systems are already far along, while solutions such as power beaming are in much earlier development phases. Overall, the group marks a shift toward software-directed operation of the physical world.

### SIGNIFICANCE OF THE TECHNOLOGY AREA

The common denominator of the group is the ability to shift sensing, movement and task execution partly or entirely from humans to machines. It addresses bottlenecks related to labor scarcity, safety risks, slow reaction, the difficulty of around-the-clock presence, and the fact that many environments are expensive, dangerous, or ergonomically poor for humans. Autonomy here does not mean a single robot, but whole systems of physical agents and the infrastructures that support them.

The strongest impact appears in transport, logistics, maintenance, inspections, semi-public spaces, and infrastructure. The group also changes ownership and power: when physical action becomes controlled by software stacks, maps, sensors, and remote operations centers, markets may concentrate in new ways. This is therefore not only about automating tools, but more broadly about who controls the physical service layer.

## DEVELOPMENT OUTLOOK

The most mature subtracks are self-driving vehicles, fully autonomous drones and robots in certain environments, and supportive infrastructure for autonomy. These already have strong regulatory, pilot, and delivery evidence. Humanoid and general-purpose robots and soft robotics appear to be progressing quickly, but the realism of deployment varies greatly by task. Optical and microwave power beaming for persistent robotics is clearly an earlier and narrower subtrack.

The group is likely to advance less through a single robot than through a whole operating system of sensors, rules, remote control, charging, infrastructure, and safety verification. Autonomy will probably move first in bounded environments where tasks are repetitive and risks manageable. What remains unclear is how quickly work roles change, to what extent citizens accept large-scale robotic presence, and how lasting the early cost advantages will be.

## ARTS IN THE GROUP

- ART 05.029 Self-Driving Vehicles — maturity: 6 — total impact score: 1044
- ART 05.030 Drone Swarms & Aerial Robots — maturity: 5 — total impact score: 485
- ART 05.031 Humanoid and General-Purpose Robots — maturity: 5 — total impact score: 985
- ART 05.032 Soft Robotics & Bio-Inspired Machines — maturity: 5 — total impact score: 355
- ART 05.033 Fully Autonomous Drones, Robots & Underwater Vehicles — maturity: 6 — total impact score: 612
- ART 05.034 Supportive Infrastructure for Autonomy — maturity: 5 — total impact score: 645
- ART 05.035 Optical/Microwave Power Beaming for Persistent Robotics — maturity: 4 — total impact score: 116
- ART 05.036 Gecko-Inspired Dry-Adhesion Mobility & Manipulation — maturity: 5 — total impact score: 115

## GROUP SUMMARY

The strength of Group 5 lies in the way it shifts the impact of radical technology into the physical environment in the most visible way. The greatest uncertainties concern safety, liability, the infrastructure costs of deployment, and social acceptance.

Strategically, the group matters because it can transform entire service models rather than merely make current processes somewhat more efficient.

## Group 6 – Additive, Agile & Digital Manufacturing

### KEY CONCLUSION

Group 6 concerns manufacturing flexibility, digital steerability, and the renewal of material forms. It is not as visibly consumer-facing as autonomy or energy, but it is an important transformation layer in the production economy: it determines how quickly products can be designed, modified, repaired, and manufactured close to demand. Maturity varies clearly; digital twins and agile production systems are already far along, while parts of 4D printing and bio-fabrication remain in earlier development phases. The group is therefore mainly enabling, but in many industrial networks it can also be directly transformative.

### SIGNIFICANCE OF THE TECHNOLOGY AREA

The common denominator of the group is the move away from rigid, long-series, and geographically dispersed production toward more rapidly adjustable, data-driven, and partly more local production. It addresses bottlenecks related to long development and lead times, high setup costs, weak production visibility, and the fact that product variation and repairability clash with the logic of mass-production optimization.

The strongest impact appears in manufacturing, maintenance, spare parts, supply-chain flexibility, and the possibilities of local production. The group can also affect how dependent companies remain on distant production hubs. At the same time, it shifts competition toward model-based definition, software integration, material expertise, and the reprogrammability of production systems.

### DEVELOPMENT OUTLOOK

Digital twin and simulation-driven production is the most mature and systematic subtrack in the group. Reconfigurable and agile factories, as well as circular and sustainable manufacturing, are also clearly on a practical development path. Multi-material and hybrid 3D printing works, but remains a more limited area of proof-of-concept and specialized use. 4D printed and programmable materials and bio-fabrication technologies are in earlier development phases, and the material does not yet indicate a broad industrial breakthrough for them.

The core of the group's development is the softwareization of manufacturing. This means that competitiveness increasingly comes from simulation, data, rapidly switchable processes, and the ability to manufacture smaller batches economically. What remains unclear is how far this really brings manufacturing closer to demand, or how quickly the cost advantage scales beyond high-skill niche applications.

## ARTS IN THE GROUP

- ART 06.037 Multi-Material & Hybrid 3D Printing — maturity: 4  
— total impact score: 348
- ART 06.038 Digital Twin & Simulation-Driven Production — maturity: 6  
— total impact score: 546
- ART 06.039 Reconfigurable & Agile Factories — maturity: 5  
— total impact score: 490
- ART 06.040 Circular & Sustainable Manufacturing — maturity: 4  
— total impact score: 356
- ART 06.041 Bio-fabrication technologies — maturity: 5 — total impact score: 190
- ART 06.042 4D Printed & Programmable Materials — maturity: 3  
— total impact score: 147
- ART 06.043 Volumetric Additive Manufacturing — maturity: 5  
— total impact score: 225

## GROUP SUMMARY

The strength of Group 6 lies in increasing the flexibility, visibility, and modifiability of production without requiring the whole industrial base to be replaced at once. The greatest uncertainties concern material acceptance, quality assurance, integration into legacy factory environments, and the speed at which new manufacturing logics become cost competitive. Strategically, the group matters because it directly affects the future shape of industrial resilience, security of supply, and production structure.

## Group 7 – Advanced Materials & Nano-engineering

### KEY CONCLUSION

Group 7 brings together material technologies whose role is to improve performance, durability, energy efficiency, and new physical properties. The group is broad and internally dispersed: it includes both very long-term ambitions such as room-temperature superconductors and solutions much closer to market, such as coatings, composites, thermal materials, and power semiconductors. The group is mostly enabling, but in some subtracks it has a clearly directly transformative role as an enabler of other shifts, especially in energy and mobility. This is precisely why it is strategically important, even when individual materials are not directly visible to the end user.

### SIGNIFICANCE OF THE TECHNOLOGY AREA

The common denominator of the group is the transformation of the material base: the conduction and storage of energy, wear, mass, thermal properties, surfaces, and component durability are being redefined. It addresses bottlenecks that arise when

current materials are no longer sufficient for lighter vehicles, more efficient powertrains, smart surfaces, safer electronics, or longer lifetimes. The group therefore often acts as a foundational layer of change for other technology groups.

The strongest impact appears in energy, transport, manufacturing, electronics, buildings, and thermal systems. The presence in the same group of power semiconductors, smart thermal materials, composites, catalysts, and advanced coatings shows that this is not one market but many critical intermediate technology layers. At the same time, materials tie development strongly to supply chains, testing, certification, and long service lives.

## DEVELOPMENT OUTLOOK

The most mature subtracks are metamaterials for novel optics and connectivity, nano-catalysts and advanced coatings, self-healing and smart polymers, and smart thermal materials. In addition, rare-earth-free magnets and several lightweight composites are progressing as usable solutions. Ultra-wide-bandgap power semiconductors still have a lower maturity classification, even though their impact potential is very high. Room-temperature superconductors are clearly the earliest and most uncertain subtrack in the group.

The group's impact is likely to come not from one giant material breakthrough, but from the accumulation of several medium-sized improvements within the same system. For example, thermal materials, coatings, lightweight composites, and power semiconductors can together change the energy balance, safety, and maintainability of an entire product. What remains unclear is the cost curve of these materials, the speed of scaling, and the extent to which environmental and recycling issues begin to limit the broad use of some solutions.

## ARTS IN THE GROUP

- ART 07.044 Metamaterials for Novel Optics & Connectivity — maturity: 6  
— total impact score: 360
- ART 07.045 Room-Temperature Superconductors — maturity: 2  
— total impact score: 134
- ART 07.046 Self-Healing & Smart Polymers — maturity: 5  
— total impact score: 300
- ART 07.047 Nano-Catalysts & Advanced Coatings — maturity: 5  
— total impact score: 310
- ART 07.048 High-Entropy Alloys & Advanced Metals — maturity: 4  
— total impact score: 188
- ART 07.049 Advanced CO<sub>2</sub> Capture Materials for Climate Mitigation — maturity: 5  
— total impact score: 155
- RT 07.050 Graphene and Nanotube Composites for Lightweight Strength  
— maturity: 4 — total impact score: 272

- ART 07.051 Smart Thermal Materials for Energy-Efficient Heating & Cooling — maturity: 5 — total impact score: 345
- ART 07.052 Rare-Earth-Free Magnets for Sustainable Motors — maturity: 4 — total impact score: 236
- ART 07.053 Nano-Engineered Membranes for Low-Energy Desalination — maturity: 6 — total impact score: 138
- ART 07.054 Ultra-Wide-Bandgap (UWBG) Power Semiconductors — maturity: 3 — total impact score: 216
- ART 07.055 Solid Hydrogen Storage Materials for Safe, Dense Fuel — maturity: 4 — total impact score: 124

## GROUP SUMMARY

The strength of Group 7 lies in its broad impact on the performance of other technology groups. The greatest uncertainties concern manufacturability, critical raw materials, long-term testing, and approval processes. Strategically, the group matters because many visible transformations only become practical once materials make them economically and technically possible.

## Group 8 – Energy Generation, Storage & Conversion

### KEY CONCLUSION

Group 8 brings together the technologies of energy generation, storage, and conversion that largely determine the cost, reliability, and emissions profile under which the rest of society can operate. The group includes both technologies close to large-scale deployment and long-term options with high uncertainty. Microgrids, grid-scale storage, solid-state batteries, and thin-film solar appear to be at the core of practical transformation, while fusion is clearly in earlier development stages. Overall, the group is directly transformative, because energy is not merely an input variable but the basis of the operating cost and reliability of all other technological changes.

### SIGNIFICANCE OF THE TECHNOLOGY AREA

The common denominator of the group is the ability to produce, store, distribute, and use energy more flexibly, more decentrally and more cleanly. It addresses bottlenecks related to electrification, peak-power management, recovery from outages, energy supply for remote sites, and the fact that many new technologies require more electricity, heat, or safe energy storage than current systems allow.

The strongest impact appears in transport, industry, buildings, distributed networks, and the resilience of society as a whole. The group also changes power relations, because it shifts competition away from centralized energy generation toward more

flexible combinations of storage, microgrids, local production, new battery technologies, and alternative fuels. This makes it not only an energy-technical field but a broader political-economic layer of change.

## DEVELOPMENT OUTLOOK

The most mature subtracks are resilient microgrids, grid-scale energy storage, and thin-film solar cells. Solid-state batteries and green hydrogen and power-to-X are developing, but already clearly strategically significant. Small modular fission reactors are further along than fusion, but their large-scale impact still depends on regulation, delivery capacity, and cost. Fusion energy reactors remain mainly in the realm of experimental and program-level development.

In most practical networks, the change in this group is likely to come through decentralization. Energy will not only be produced more cleanly, but also stored, transferred, and prioritized more locally. This makes microgrids and storage strategically more important than one might conclude from looking at a single production form. What remains unclear is when the total costs of different energy technologies settle permanently at new levels, or how quickly bottlenecks in electrification ease across sectors.

## ARTS IN THE GROUP

- ART 08.056 Fusion Energy Reactors — maturity: 3 — total impact score: 219
- ART 08.057 Small Modular Fission Reactors (SMRs) — maturity: 5 — total impact score: 325
- ART 08.058 Thin-film solar cells — maturity: 6 — total impact score: 510
- ART 08.059 Bionic Leaf Technology — maturity: 4 — total impact score: 88
- ART 08.060 Grid-Scale Energy Storage — maturity: 6 — total impact score: 612
- ART 08.061 Solid-State Batteries — maturity: 5 — total impact score: 535
- ART 08.062 Green Hydrogen & Power-to-X — maturity: 5 — total impact score: 430
- ART 08.063 High-Efficiency Wind Turbines — maturity: 6 — total impact score: 294
- ART 08.064 Wireless & Space-Based Power Transfer — maturity: 3 — total impact score: 75
- ART 08.065 Advanced geothermal technology — maturity: 4 — total impact score: 228
- ART 08.066 Resilient microgrids — maturity: 6 — total impact score: 744

## GROUP SUMMARY

The strength of Group 8 lies in its direct connection to nearly all other technology groups: without energy there is no electrification, no distributed automation, and no computation-intensive systems. The greatest uncertainties concern scale, regulation,

system integration, and material dependencies. Strategically, the group matters because the energy system determines how quickly the wider technological transition can become part of everyday life in an economically sustainable way.

## Group 9 – Bio-engineering & Life-Science Technologies

### KEY CONCLUSION

Group 9 brings together breakthroughs in bioengineering, genetic technologies and biomedicine that can transform health, nutrition, materials, and biological production. The group is highly heterogeneous: some technologies, such as mRNA platforms and precision diagnostics, are already fairly mature, while artificial wombs or gene-drive solutions are earlier and much more socially contested. The group is both directly transformative and strongly institutional, because many effects depend on clinical evidence, regulation, and social acceptance. It changes not only production or services, but also the operating logic of the human body, disease, and biological design.

### SIGNIFICANCE OF THE TECHNOLOGY AREA

The common denominator of the group is the programmability of biological processes. It addresses bottlenecks related to the precision of care, biological production, the sustainability of nutrition, the design of biological materials, and the fact that many current medical and productive processes are slow, coarse, or difficult to personalize. In this group, biology becomes part of a design and development platform rather than only a natural resource or an object of intervention.

The strongest impact appears in health care, nutrition, biomaterials and, in the longer term, also in disability, aging, and societal risk management. At the same time, the group brings with it an exceptional number of ethical, regulatory, and social boundaries that do not appear in the same way with purely digital technologies. For this reason, market potential and deployability do not always advance at the same pace.

### DEVELOPMENT OUTLOOK

The most mature subtracks are mRNA therapies and vaccines and precision medicine and genomic diagnostics. Next-generation gene editing, synthetic biology, and cellular agriculture are emerging but already clearly credible and fast-moving. Engineered living materials, gene-drive pest control, and artificial wombs and synthetic embryos are in much earlier development phases or more strongly conditioned by social acceptance. Microbiome engineering also appears promising, but as a fragmented field.

The next phase of change is likely to be built around platform logic. mRNA, gene editing, synthetic biology, and diagnostics are not only individual products, but are beginning to function as generic development and manufacturing platforms.

This may accelerate the creation of new products, but may also concentrate expertise, data, and regulatory capability in the hands of a small number of actors. What remains unclear is how quickly acceptance broadens into large-scale consumer or clinical use, or how strongly ethical boundaries shape the progress of different sub-tracks.

## ARTS IN THE GROUP

- ART 09.067 Next-Generation Gene Editing — maturity: 5  
— total impact score: 330
- ART 09.068 mRNA Therapies & Vaccines — maturity: 6 — total impact score: 288
- ART 09.069 Cellular Agriculture & Cultured Meat — maturity: 5  
— total impact score: 345
- ART 09.070 Organoids & Tissue Engineering — maturity: 5  
— total impact score: 170
- ART 09.071 Synthetic Biology & Designer Microbes — maturity: 5  
— total impact score: 380
- ART 09.072 Microbiome Engineering — maturity: 5 — total impact score: 170
- ART 09.073 Precision Medicine & Genomic Diagnostics — maturity: 6  
— total impact score: 456
- ART 09.074 Organs-on-Chips & Bio-Computational Hybrids — maturity: 4  
— total impact score: 104
- ART 09.075 Biological Aging & Longevity Barriers — maturity: 4  
— total impact score: 320
- ART 09.076 Engineered Living Materials — maturity: 3 — total impact score: 171
- ART 09.077 Gene Drive Pest Control — maturity: 3 — total impact score: 111
- ART 09.078 Artificial Wombs & Synthetic Embryos — maturity: 3  
— total impact score: 90

## GROUP SUMMARY

The strength of Group 9 lies in opening entirely new ways to treat, produce, and design biological systems. The greatest uncertainties concern safety, long-term effects, regulation, and social acceptance. Strategically, the group matters because it can generate both very high-value health and production platforms and, at the same time, new political and ethical fault lines.

# Group 10 – Space & Aeronautical Engineering

## KEY CONCLUSION

Group 10 is the smallest group, but the contrast within it is large: on the one hand it includes a fairly mature satellite-based connectivity infrastructure, and on the other, very long-term space-resource and life-support systems. The group matters

because it extends infrastructure above the atmosphere and makes communication, observation, and resource acquisition partly space dependent. At present the group is primarily enabling, but ART 10.079 shows that even one subtrack can already be highly influential. Overall, this remains a technology area with uneven maturity.

## **SIGNIFICANCE OF THE TECHNOLOGY AREA**

The common denominator of the group is the relocation of infrastructure away from the Earth's surface. It addresses bottlenecks related to global coverage, connectivity in remote areas, crisis resilience, broad fields of observation and, in the very long term, scarce resources. In practice, this means that some critical societal functions increasingly rely on satellites, high-altitude platforms, and other space- or atmosphere-based solutions.

The strongest impact appears in communications, positioning, remote sensing, and services in exceptional conditions. Space resource utilization and closed-loop life support are much more immature in comparison, but they broaden thinking about what counts as a realistic environment for production or life support. The group is therefore strategically important, especially from the perspective of resilience and long-term geopolitical dependence.

## **DEVELOPMENT OUTLOOK**

Satellite mega-constellations and space internet are clearly the most mature and broadest-impact subtrack in the group. High-altitude platforms and balloons are also a usable and developing infrastructure solution, even if their impact is more limited. Closed-loop life support is an intermediate technology whose practical applications are still far from everyday markets. Space resource utilization is the most immature and most uncertain technology in the group.

The group's near-term impact is likely to concentrate almost entirely on communication and wide-area observation, while the significance of resource utilization and closed systems remains a longer-term strategic option. What remains unclear is how the regulation, security, and geopolitical concentration of space infrastructure affect the pace of adoption. The long-term cost trajectory is also difficult to assess in detail.

## **ARTS IN THE GROUP**

- ART 10.079 Satellite Mega-Constellations & Space Internet — maturity: 6  
— total impact score: 888
- ART 10.080 Space Resource Utilization (SRU) — maturity: 3  
— total impact score: 39
- ART 10.081 Closed-Loop Life Support System — maturity: 4  
— total impact score: 16
- ART 10.082 High-Altitude Platforms & Balloons — maturity: 5  
— total impact score: 300

## **GROUP SUMMARY**

The strength of Group 10 lies in offering an alternative infrastructure layer in situations where terrestrial solutions are slow, expensive, or vulnerable. The greatest uncertainties concern geopolitical dependence, security, and whether the impact remains concentrated in a few infrastructure lines or later expands into resource and production systems. Strategically, the group matters because its most mature subtrack is already highly influential, even though the rest of the group is in a much earlier development stage.

## **Group 11 – Digital Platforms & Collective-Intelligence Systems**

### **KEY CONCLUSION**

Group 11 brings together technologies for digital platforms, trust, data exchange, and collective organization. Its maturity is relatively strong: most ARTs lie in the upper middle range, and some are already close to broad practical use. The group matters less because it changes a single physical process and more because it changes how people, organizations, and networks coordinate, share data, learn, and govern common resources. This is therefore above all an institutional and governance transition.

### **SIGNIFICANCE OF THE TECHNOLOGY AREA**

The common denominator of the group is a new logic of digital coordination. It addresses bottlenecks related to lack of trust, the difficulty of sharing data, the scalability of collective action, platform power, and the fact that current digital markets and communities are often either too centralized or too fragile. The group's technologies offer alternative ways to govern transactions, open innovation networks, learning networks, foresight, and cooperatively owned services.

The strongest impact appears in platforms, data markets, education, community organization, and new trust architectures. Many technologies in the group derive their value not only from software, but from whether practices, standards, and accepted governance models emerge around them. The group is therefore both a technical and a social infrastructure.

### **DEVELOPMENT OUTLOOK**

The most mature and strongest subtracks are decentralized trust networks, open data sharing marketplaces, collective open innovation networks, and digital learning networks and skill credentialing. Secure and resilient social platforms and scalable decentralized governance also appear to be developing credibly. Platform cooperatives and fair work are among the lower-maturity subtracks, not because the model is theoretical, but because economic scale-up and competitive position against large platforms remain uncertain.

The main bottlenecks in the group are not primarily algorithmic but governance-related. Technical solutions can be built, but their value depends on accepted rules, trust between actors, regulation, and network effects. This favors solutions that can connect to existing practices rather than only offering a technically superior model. What remains unclear is to what extent decentralized models truly break platform concentration or remain niche and institution-specific alternatives.

## **ARTS IN THE GROUP**

- ART 11.083 Decentralized Trust Networks (Web3 & Blockchain) — maturity: 6  
— total impact score: 654
- ART 11.084 Platform Cooperatives & Fair Work — maturity: 4  
— total impact score: 416
- ART 11.085 Open Data Sharing Marketplaces — maturity: 6  
— total impact score: 576
- ART 11.086 Secure & Resilient Social Platforms — maturity: 5  
— total impact score: 475
- ART 11.087 Collective Open Innovation Networks — maturity: 6  
— total impact score: 504
- ART 11.088 Scalable Decentralized Governance — maturity: 5  
— total impact score: 410
- ART 11.089 Digital Learning Networks and Skill Credentialing — maturity: 5  
— total impact score: 585
- ART 11.090 Prediction-Market Forecasting Platforms — maturity: 7  
— total impact score: 378

## **GROUP SUMMARY**

The strength of Group 11 lies in its ability to change the rules of coordination, trust, and data sharing without rebuilding all physical infrastructure from scratch. The greatest uncertainties concern network effects, the viability of governance models, and the speed at which new trust solutions can displace today's centralized platforms. Strategically, the group matters because this layer increasingly determines who gets the data, who organizes the community, and who controls the digital distribution of value.

## **Group 12 – Protocols, Standards & Socio-Technical Infrastructure**

### **KEY CONCLUSION**

Group 12 brings together the protocols, standards and socio-technical infrastructure that make other technologies interoperable, auditable, and governable. The group is strategically exceptional because it directly determines whether future technologies

become fragmented point solutions or scalable ecosystems. Maturity is mostly above the midpoint: many subtracks are not yet fully established, but they are already supported by standards, recommendations, and deployment paths. The group is clearly enabling, but in many networks it is also directly transformative because it changes the enforcement of rules and the interplay between systems.

## **SIGNIFICANCE OF THE TECHNOLOGY AREA**

The common denominator of the group is the language of coordination. It addresses bottlenecks related to system incompatibility, data portability, the slow implementation of regulation, the portability of identity and payments, and the fact that without standards each technology scales only within its own closed ecosystem. The group makes the other groups practically governable and connectable.

The strongest impact appears in IoT ecosystems, data transfer, identity, payments, regulation, the portability of digital twins and collaboration-protecting protocols. At the same time, the group shifts power toward standard setters, certifiers, trust frameworks and the actors that control the machine-readable implementation of rules. This makes it a core area of technology policy.

## **DEVELOPMENT OUTLOOK**

The strongest subtracks in the group are universal IoT interoperability standards, machine-readable regulation, content authenticity infrastructure, personal data portability and trust frameworks, and global supply chain traceability networks. Interoperable digital twin ecosystems and privacy-preserving collaboration protocols are also clearly developing and strategically important. Interoperable digital currency payment networks are in somewhat earlier development phases, or at least more institutionally contingent, than many other technologies in the group.

The impact of the group is likely to grow as the wider technological environment becomes more complex. When automation, sensors, identities, and payments are connected, standards and machine-readable regulations no longer support functions but conditions of operability. This may accelerate deployment, but it may also increase dependence on a small number of actors in the standards and trust layer. What remains unclear is when certain protocols reach de facto status or how strongly geopolitical differences fragment the standards landscape.

## **ARTS IN THE GROUP**

- ART 12.091 Universal IoT Interoperability Standards — maturity: 5  
— total impact score: 820
- ART 12.092 Interoperable Digital Twin Ecosystems — maturity: 5  
— total impact score: 560
- ART 12.093 Global Supply Chain Traceability Networks — maturity: 5  
— total impact score: 655
- ART 12.094 Personal Data Portability & Trust Frameworks — maturity: 5  
— total impact score: 665

- ART 12.095 Interoperable Digital Currency Payment Networks — maturity: 4  
— total impact score: 356
- ART 12.096 Machine-Readable Regulation (Rules as Code) — maturity: 5  
— total impact score: 705
- ART 12.097 Open Metaverse Interoperability Protocols — maturity: 5  
— total impact score: 290
- ART 12.098 Content Authenticity Infrastructure — maturity: 6  
— total impact score: 678
- ART 12.099 Privacy-Preserving Collaboration Protocols — maturity: 4  
— total impact score: 464
- ART 12.100 Manufacturing-specific Standards, Conformance Testing & Certification Infrastructure — maturity: 5 — total impact score: 550

## GROUP SUMMARY

The strength of Group 12 lies in turning individual technologies into ecosystems. The greatest uncertainties concern ownership of standards, the power of certification, shared cybersecurity failure risks, and how open the resulting practices truly remain. Strategically, the group matters because this layer is likely to become one of the most important arenas of competition and regulation across the whole radical technology transition.

# Methodology

## Principles of Radical Technological Inquirer

The present study is the latest foresight iteration using the Radical Technology Inquirer (RTI) methodology developed for the Committee for the Future of the Finnish Parliament. In the RTI framework, the anticipation of technological change does not begin from single inventions alone, nor only from abstract societal megatrends. Instead, it combines a technology-oriented perspective with a societal need- and value-oriented perspective. The former concerns the identification and grouping of anticipated radical technologies (ARTs), which might solve technological bottlenecks in value production, while the latter concerns their assessment in relation to broad societal value-producing networks (GVNs), their dominant and challenger regimes, and the changing ways in which societal needs may be met. The purpose of the methodology is not to describe which technologies are currently dominant, but to identify from which directions the challengers to currently dominant socio-technical arrangements are emerging and what their various impacts may be. RTI is a methodology for anticipating societal transformation rather than for merely cataloguing technical novelty.

Historically, RTI should be understood not as a single report-specific invention, but as an iterative foresight framework that has developed through successive rounds of application, evaluation, and refinement. Here, only reports that contributed to the development of RTI are mentioned and listed in references. According to the report tradition, the development of the method began in 2012, and the first monitoring round was conducted in 2013 (Linturi et al., 2013). In 2016, a follow-up report (Linturi, 2016) assessed how each anticipated development had evolved and how the method could be further developed. The 2018 report (Linturi & Kuusi, 2018) implemented these suggestions and represented a substantially expanded

and methodologically refined continuation of that earlier work while preserving the same basic analytical logic. In 2022, RTI was described in detail as a methodology that can be repeated in a peer reviewed journal EJFR (Linturi et al., 2022). Thereafter, preparing further development, in 2025 a pilot report (Björkroth et al., 2025) focused on one anticipated radical technology, humanoid robotics, providing one further iterative step in which the method's most labor-intensive phases were renewed through AI assistance while the core framework remained intact.

The core structure of RTI rests on two elements. First, society is modeled through twenty value creation networks that cover broad and organized forms of value creation, such as transport, logistics, exchange, health care, and acquiring information. Within each value creation network, RTI distinguishes between a dominant regime and a challenger regime. The dominant regime describes the currently prevailing way in which value is created; the challenger regime describes a plausible future direction in which emerging technologies, changing practices, and new institutional arrangements may reorganize value creation. Second, RTI treats radical technologies as general-purpose means rather than as solutions locked to one sector. This is methodologically important because the same technology may transform several different value creation networks, and because transformative effects often arise precisely when a technology developed in one context diffuses into another. A practical example is the development of lithium-ion batteries. Although their early commercial development was strongly linked to portable consumer electronics, especially mobile phones, their wider significance emerged much later in another domain. Improvements in energy density, reliability, and manufacturability made it possible for lithium-ion batteries to become one of the central enabling technologies of the electric vehicle transition. In this sense, the most consequential societal effects of the technology did not remain confined to the sector in which its development was first accelerated. Instead, they appeared through cross-sectoral diffusion, when a technology developed for one purpose began to reorganize transport, energy systems, industrial value chains, and related policy choices. One of the central strengths of RTI is that it is able to make such spillover effects visible.

In practical RTI work, this logic has been operationalized through a phased process. In the full implementation, the method includes the identification and grouping of anticipated radical technologies, their maturity assessment, the definition of twenty value creation networks, the qualitative creation of weak signals linking technologies to those networks, and the scoring of transformative significance on a logarithmic scale. The 2018 report (Linturi & Kuusi, 2018) carried out this work as a broad national foresight exercise based on extensive crowdsourced and expert-supported source gathering. The 2025 pilot retained the same basic architecture but focused on one technology family, humanoid robots, and concentrated AI use especially in refining the value creation network descriptions for AI use, identifying future impacts, and evaluating their significance.

The present study follows these same core RTI principles documented in detail in the EJFR 2022 article (Linturi et al., 2022). It retains the view that technological change must be interpreted through value creation networks, that transformation

concerns both direct and indirect societal effects, and that technologies must be assessed as potential contributors to wider challenger regimes rather than as isolated gadgets. At the same time, the study differs methodologically from both RTI 2018 (Linturi & Kuusi, 2018) and the 2025 (Björkroth et al., 2025) pilot report in one important respect: AI was not used only to accelerate the identification of societal effects, but also much earlier in the process, in the generation, curation, description, and evidencing of the ART set itself. This also made it possible to operationalize the ART concept more rigorously than before by identifying and describing ARTs as generic groups of potential solutions promising to open bottlenecks in value chains or capability bundles in a similar sense, outlined in the RTI methodology literature, rather than merely as lists of promising technologies. In this respect, the present round can be seen as bringing the practical ART-identification process more closely into line with the conceptual logic articulated in the defining EJFR article.

A central principle of the present implementation was therefore continuity with RTI at the level of analytical logic, combined with methodological renewal at the level of workflow. The study did not seek to invent a new foresight method from scratch. Rather, it asked whether the RTI process could be updated so that AI would support the production of a full ART and GVN assessment while the research team remained responsible for framing, selection, validation, and interpretation. This principle also explains why the method places emphasis on structured prompting, explicit scoring rules, source-quality hierarchies, manual checking, and iterative refinement, rather than on unconstrained generative output.

## Using AI according to Radical Technology Inquirer principles

The use of AI in this study followed a deliberate attempt to distinguish between loosely generative output and methodologically disciplined AI-assisted foresight. In the 2025 (Björkroth et al., 2025) pilot, one of the main methodological findings was that large language models could produce broad and sometimes exceptionally rich societal impact analyses when they were guided by a strong analytical framework, whereas open-ended prompting tended to generate more conventional and less useful answers. The pilot also emphasized that the quality of results depends fundamentally on the quality of the questions posed to the model. This observation was adopted here as a starting point. AI was not treated as an autonomous analyst, but as a structured inference and synthesis tool operating within the RTI framework.

In practice, this meant that AI use was organized as a sequence of bounded tasks rather than as one continuous conversation. The process began with AI-assisted identification of broad technology domains and bottlenecks in which candidates for anticipated radical technologies might be emerging. Instead of relying on volunteer-based gathering of technology news, as in the earlier RTI rounds, or on manual researcher-led prospecting for a single focal technology, as in the pilot, the present study used AI as an upstream prospecting instrument. The aim was first to identify

where potentially significant technological developments might be located, and only then to move toward candidate ARTs. In methodological terms, this altered the origin of the prospect list while keeping intact the later RTI logic of grouping, description, and impact assessment. Quantitatively, this structured inference and synthesis meant a staged screening process in which searches were first widened technology group by technology group and then narrowed through successive filtering, summarization, elimination of overlap, and recombination. In rough terms, the AI-assisted process made it possible to read and screen tens of thousands of articles and documents, from which around two thousand more relevant items were filtered into a working corpus for further synthesis. Compared with purely manual work, the gain was not only speed but also the ability to carry out a much broader and more systematic first-pass scan before the researcher-led curation and interpretation phases began.

The candidate ART list produced in this way was not accepted automatically. The research team reviewed the prospect list manually, identified duplicates, removed technologies judged to be too mature, too marginal, or insufficiently radical for the purposes of the exercise, and in some cases reassigned items to more suitable technology groups. This human curation phase was indispensable. It ensured that AI-assisted prospecting would not determine the final ART set on its own, and that the resulting technology portfolio remained conceptually coherent from the standpoint of RTI. Only after this curation step were the retained ARTs expanded into fuller descriptions with AI assistance.

The ART descriptions were then written in a standardized form designed to remain sufficiently generic for later cross-GVN analysis. This again followed an RTI principle already visible in the pilot: ARTs should not be described so narrowly that their future uses are predetermined in advance. The AI-assisted descriptions therefore emphasized the capability of the technology, the kinds of bottlenecks it could plausibly address, its dependencies and constraints, and the sort of mature technological bundle it might represent. In this way, the descriptions functioned as analytical inputs for later societal-impact analysis for generative AI, rather than as mini market reports.

A further AI-assisted phase consisted of creating evidence dossiers for each ART (for final curated dossiers, see Attachment 2). Here too the objective was not open-ended content generation, but a constrained evidencing task. Each ART description was entered into a standardized Deep Research prompt that asked the model to produce a compact dossier of recent sources, prioritize peer-reviewed and otherwise authoritative evidence, and assign a single maturity score on the RTI 1–7 scale for the ART. The prompt required a single integrated analysis of the technology bundle rather than separate scores for subcomponents, and it explicitly specified a four-year publication window, a hierarchy of acceptable source types, and a distinction between plausibility and maturity.

Importantly, these evidence dossiers were not treated as final outputs. The dossier documents were reviewed by researchers, links were checked manually, and problematic cases such as missing or misdirected sources were identified and discussed within the research team. This procedure was necessary not only because large language models may hallucinate sources or misclassify their relevance, but also because the source-selection logic or described ART definition itself can produce skewed representations. One concrete example concerned the self-driving vehicle dossier, where the evidence selection underrepresented Tesla despite the company's public salience in the field. Whether this reflected prompt bias, source-availability effects, model behavior, or some combination of these could not be resolved conclusively, but the case demonstrated that even technically strong prompts require human review for completeness and balance. In the methodology of this study, transparency about such cases is preferable to overclaiming flawless AI-supported evidence gathering.

The most consequential AI-assisted phase concerned the creation of weak signals and impact scoring for ART-GVN pairs. Here the study adopted the “AI-optimized” GVN descriptions from the 2025 pilot report as the basis for prompting, because those descriptions had already been refined for use with large language models. In methodological terms, the most desirable option would have been a single integrated analysis in which all ARTs and all GVNs were assessed together, since this would most fully reflect the RTI ambition of examining technological transformation as an interacting whole. In practice, however, this was not feasible with the available model context limits: such runs became too shallow, and the analytical depth did not remain at a satisfactory level. For that reason, two more bounded alternatives were compared in benchmarking: analyzing one ART across all GVNs, and analyzing all ARTs within one GVN. The level of depth in the resulting analyses proved broadly similar, but the latter option was considered methodologically preferable. Instead of implicitly treating each ART as if it developed in isolation, a GVN-specific run allowed the model to assess technologies in relation to one another within the same sociotechnical field. This made it easier for the model to identify spillovers, complementarities, substitution effects, and institutional interactions inside a given value creation network, and thus better matched a central RTI insight: radical technologies develop side by side and simultaneously, not as isolated trajectories.

The prompt used for this phase was strongly structured (see Attachment 6 for details in scoring maturity and impact). It asked the model to assume each ART in a mature state, to score each ART for the selected GVN using the discrete RTI scale of 0, 1, 3, 5, 10, or 20, and to interpret impact magnitude in relation to a rough western-society baseline of 5.5 million inhabitants. The prompt also explicitly required that the model include 1st-order, 2nd-order, and 3rd-order pathways in its assessment and that the score reflect the largest plausible total impact magnitude across these layers rather than only direct operational effects. In addition, it defined weak signals as observable early indicators of a pathway and included an explicit low-density rule for cases where a linkage was weak. In RTI, weak signals are short interpretive statements derived from observable developments that may indicate a wider emerg-

ing pathway of change. Thus, an observed technical capability such as increasingly autonomous vehicle operation is treated not merely as a “fact in itself”, but as a possible signal of broader future developments such as the emergence of robotaxi services. All these prompt elements were designed to counter direct-use bias, false precision, and generic filler in a manner that would not impact the direction of results.

This part of the process also involved methodological calibration. The 2025 pilot’s humanoid-robot analysis was used as a checkpoint for what the pilot had termed “intelligent creative tension,” that is, the deliberate forcing of the model to explore interactions between a radical technology and the goals, values, and structures of a value creation network. In early iterations of the present prompt, second- and third-order effects often appeared in the narrative justification but were not clearly enough reflected in the actual score assignment. For that reason, the prompt was revised so that systemic and spillover effects would shape not only the wording of the analysis but also the formal scoring outcome. This tuning process should be understood as part of the method itself rather than as a purely technical adjustment, because in RTI the quality of the scoring depends directly on how well indirect and cross-sectoral pathways are captured.

As an assessment of the renewed methodology, it can be said that AI was used according to RTI principles as four conditions were met. First, the model was given a clearly bounded analytical task. Second, each task was embedded in a strong conceptual structure, especially the ART and GVN descriptions and the RTI scoring logic. Third, the outputs were subject to manual review and iterative correction. Fourth, the process remained transparent about its own limitations. This is also why the study does not describe AI as an independent researcher. It functioned instead as a catalyst for broader search, richer combinatorial analysis, and more consistent formalization, while the human research team retained responsibility for design choices, relevance judgments, and the final interpretation of outputs.

A further consequence of this AI-assisted operationalization was that the 2025 pilot, and especially the present full RTI iteration, were able to capture both positive and negative potential impacts more broadly and more evenly than the 2018 version. This reflected not only a deliberate methodological choice, but also the practical affordances of AI-assisted analysis: the report no longer had to be constrained to a narrowly human-scale format, and alternative prompt versions could be tested repeatedly on large masses of material at a fraction of the effort that comparable manual operationalization would have required. In practice, this is also visible in the scale of the outputs themselves: the 2018 RTI report extended to 483 pages, the 2025 humanoid-robot pilot to 271 pages, and the present 2026 full RTI material to well over 2 000 pages. This expansion in length should not be understood merely as verbosity, but as an indication that opportunities, risks, inhibiting factors, and cross-effects could now be documented in much greater breadth than was previously feasible. This can especially be seen in Attachment 2 in how each ART is broken into subtasks and analysed, but also in Attachment 3, how ART – GVN impacts are broken into a list of weak signals that is much more widespread than in 2018 report. This present study is not more verbose, it has much larger number of perceptions.

## AI-assisted RTI: framework validation, limitations, and next development steps

The broader AI-assisted workflow used in the present iteration affected not only how the ART set was identified and analyzed, but also how the resulting material had to be organized. Because the project now produced a much larger and more layered corpus of ART descriptions, impact assessments, weak signals, and supporting evidence than in earlier rounds, it became necessary to structure that material in a form that could support consistent retrieval, comparison, and synthesis across the project. The 2018 report already had a rigorous structure sufficient in principle, but to make the results fully explorable with a tailored RTI-GPT model, it needed finetuning.

To meet this need, the material was structured in separate files, each with a topic based record or data-card-like structure and a map-like table showing which ART's impact which GVN. In practice, this meant structuring the data so that corresponding ARTs, GVN, scores, weak signals, and descriptions were systematically named and each type of data found in specific file, and giving the model explicit instructions on where to find and how to identify the relevant matching entries when generating responses. The current report draft of the technology-group and GVN summary sections was produced with the help of this RTI-GPT using RAG-type retrieval. Its role was not merely to reproduce stored content, but to support systematic retrieval, comparison, and synthesis from the project corpus in a more consistent way than would have been practical through manual querying alone. The RTI-GPT was also tested internally through a structured question set and by research team members in different use scenarios. Methodologically, this should still be understood as a supporting interpretive and summarizing tool rather than as a separate analytical phase of RTI itself.

More important than the RTI-GPT was the question of whether the GVN descriptions themselves remained analytically valid. The 2025 pilot (Björkroth et al., 2025) had already emphasized that refining value creation network descriptions was crucial for good AI-assisted analysis. In that pilot, the 2018 descriptions were considered sufficiently up to date to serve as a basis, but they were reformulated for AI use and separated more clearly into goals, values, and regime descriptions. The present study inherited those AI-optimized GVN descriptions and used them in the ART  $\times$  GVN analysis phase. This created continuity across the method, but it also made it possible to observe where the old transformation logics remained persuasive and where they had become outdated or incomplete.

On the whole, the GVN framework remained in good condition. Most of the twenty value creation networks still offered analytically believable descriptions of dominant and challenger regimes, and they remained usable as scaffolds for systematic AI-assisted impact assessment. This is in itself a noteworthy result, because it suggests that the core RTI sociotechnical architecture has retained much of its explanatory value over the period from 2018 to 2026. At the same time, the study also found

that one GVN, Acquiring Information (GVN 14), now raises more substantial questions about the direction of transformation than was assumed in the earlier framework.

The challenge in GVN 14 does not appear to be that information acquisition has failed to become more data-rich, personalized, platform-mediated, or AI-assisted. On the contrary, those parts of the challenger direction have largely moved as anticipated. The more serious issue concerns credibility and trust. The earlier transformation logic assumed, in effect, that the movement toward more distributed, source-proximate, AI-assisted, and peer-supported information acquisition would also improve relevance and plausibility. Current development appears more contradictory. Relevance and personalization have increased, but credibility has not improved in the same movement. Instead, platform dependence, synthetic content, provenance uncertainty, and weakened common information environments have increased the need for authenticity infrastructures, content labeling, provenance standards, and new forms of technical and regulatory verification. In this respect, the transformation has not simply proceeded from centralized authoritative information toward better distributed knowing; it has also generated a stronger need for institutional and technical trust layers. This makes GVN 14 the clearest case in which the challenger direction itself should be reconsidered in the next RTI iteration.

At the same time, this framework-level weakness did not mean that the RTI-GPT or the report itself merely reproduced an outdated original transformation logic mechanically. On the contrary, in the generated report material the model often produced more credible and analytically balanced formulations than a literal reading of the inherited GVN description alone might have suggested. This is methodologically significant. It indicates that a well-configured large language model can interpret, synthesize, and reorganize the material rather than simply restate it. In that sense, the RTI-GPT functioned not only as a retrieval and summarization tool but also as a useful interpretive layer within the broader research process.

This positive result does not, however, remove the need for conceptual revision. If a model produces a more plausible output despite weaknesses in the underlying GVN definition, that should be treated as evidence of model-level interpretive capacity, not as proof that the framework itself remains fully adequate. The broader methodological conclusion is therefore twofold. First, AI can assist RTI-style work not only by accelerating analysis but also by revealing where inherited conceptual structures no longer fit present developments cleanly. Second, the most immediate next development step should be a systematic update of the GVN descriptions before the next full RTI round. Such an update should focus especially on those domains in which the sociotechnical environment has changed most rapidly since 2018, including acquiring information, collaboration and trust, and possibly also work and income, where platform concentration and infrastructural centralization have in several respects proceeded more strongly than earlier challenger-regime descriptions implied. In that sense, the present round should be seen both as a completed foresight exercise and as part of the iterative development that is intrinsic to

RTI. It functions not as a final methodological endpoint, but as one stage in the continuing refinement of the framework and, in that respect, as a bridge toward a renewed RTI architecture.

One AI-driven difference between these reports should also be noted. In the present report, the component technologies of ART development were identified, and their maturity was assessed at a considerably finer level of detail than in the 2018 report. Likewise, the weak signals were described much more precisely than in 2018, although not at the same level of granularity as in the 2025 (humanoid-robot) pilot. This reflected a practical trade-off built into the present iteration: whereas the pilot could devote multiple iterative weak-signal runs to a single ART, the full RTI exercise had to extend comparable logic across 100 ARTs. The result was therefore substantially more fine-grained than the 2018 iteration, but necessarily less detailed per individual ART than a single-technology pilot could be.

A final limitation should be stated explicitly. However structured the prompts and however extensive the manual checking, AI-assisted foresight remains sensitive to prompt design, source selection, model behavior, and corpus structure. It can widen the search space, accelerate synthesis, and formalize impact comparisons more consistently than unaided manual work. It does not eliminate the need for interpretation, selection, or conceptual judgment. The value of the present method lies not in removing human responsibility, but in reallocating human effort from repetitive collection and first-pass combinatorial work toward framing, checking, and methodological reflection. This was also the underlying principle of the 2025 pilot, and it remains the most defensible way of understanding AI-assisted RTI in the present study.

It is also important to place the present methodological experiment in a wider context. The rapid diffusion of generative AI has been accompanied by a growing volume of low-quality, weakly verified, and poorly accountable content, often described in public discussion as “AI slop.” In such uses, AI typically accelerates output without a corresponding increase in transparency, source criticism, or conceptual discipline. The present study has aimed in the opposite direction. Rather than using AI as a shortcut around analysis, it has sought to embed AI within a demanding foresight framework in which concepts, prompts, source hierarchies, scoring rules, and human review constrain what the model is allowed to do. In this sense, the AI-fication of RTI should be understood as an attempt to place new generative tools under rigorous methodological use and, by doing so, to demonstrate what they can contribute when they are not treated as substitutes for judgment, expertise, or responsibility.

Given all this, what about the future of RTI? How much foresight automation will AI eventually enable? Certainly, more than now, but while AI greatly facilitates the gathering of ART evidence and respective societal impact assessment, human reflection cannot fully be removed from the equation. Full AI-fication of RTI would mean that AI were able to inherently understand what we as individual humans and human societies wish to pursue. It is unlikely that the RTI-methodology would ever

be perfected to find the “final” form without human intuition. Thus, methodological decisions will always require at least human confirmation. Human aspirations are not deductions of previous understanding. One cannot logically derive a statement about what ought to be done solely from statements about what is the case, as David Hume’s guillotine famously states. We also pragmatically know from the earlier RTI update rounds that the accumulation of new evidence tends to necessitate reformulation of categories, as technological evolution renders some earlier conceptualizations obsolete and calls for new ones. AI can naturally be used to suggest new formulations, but do they resonate with our aspirations? Approving them needs to be done consciously by humans. Moreover, RTI methodology requires that the systemic implications of all the new evidence be considered and weighted jointly. This all means that the updating of the RTI results will also in the foreseeable future need to take place periodically in a human-led process rather than automatically and continually. But real time considerations partial as they may be, become easier than before. And RTI-GPT is one example in this regard.

# Conclusions

## What should policymakers pay attention to?

For policymakers, the relevant question is whether governance systems are capable of adapting to technological shifts before institutional lag itself becomes a bottleneck. The report shows the development status and maturity of each of the 100 assessed technologies in 2025-26, indicating which ones are likely to enter the markets fastest. But more importantly, the results reveal that radical technologies enable and encourage societal transformations which require different forms of coordination, certification, liability allocation, and institutional competence than ones that support the extant ways of value creation.

In logistics, for example, the dominant regime is still tied to industry- and trade-centric logistics, shared infrastructure with passenger transport, large shipments, consumer self-transport, and adherence to established norms and regulatory frameworks. By contrast, the emerging challenger regime is built around smart robotization, autonomous vehicles and drones, open digital platforms, cloud-based control services, and shared smart lockers. While opinions may differ on the desirability of such change, the essential questions are whether the change is already occurring in some places; why would it spread; what its spreading would mean for our society's value-creation; what we should do about it? The policymakers' attention should be directed toward identifying the points where old institutional arrangements and related regulation cease to match emerging operating models. The border between legitimate risk management and unnecessary lock-in to the old way of doing things should be actively scrutinized and debated. Failing this, the likely outcome is not the prevention of change but becoming its victim: jurisdictions, sectors, or actors better able to experiment, learn, and scale will lead the way. Thus, public institutions need alertness not only to risks, but also to timing.

Policymakers should also pay attention to the second and third-order impacts caused by new technological capabilities. What are the anticipated shifts in labor relations, liability, insurance, market structure, urban planning, and bargaining power? Who gains control over standards, compliance interfaces, data flows, software layers, and certification pathways as adoption proceeds? Technological transitions are also governance transitions: they can redistribute advantage between incumbents and entrants, between public authorities and private platforms, and between actors with differing capacities to absorb uncertainty, invest in new systems, or shape the rules of the game.

This points to a broader use of the report, and by extension to the use of the Radical Technology Inquirer GPT (RTI-GPT), as a policy tool. The value of the report is not only that it highlights technologies that may become important, but it offers a way to ask which institutional arrangements remain robust under challenger-regime conditions, which become bottlenecks, and which leave public responses systematically reactive rather than anticipatory. The task is to recognize early where technological change is likely to produce system-level consequences, where weak signals already indicate that institutional adaptation is becoming urgent, and where governance itself may become either an enabling capacity or an unintended barrier. RTI-GPT is equipped to retrieve answers to such questions from its database.

We believe that possibly the best way to think of this report and RTI-GPT as its reading method as a tool that helps to understand and anticipate potential cross-sectoral implications of technological change. To approach such systemic changes in a comprehensive manner is not as easy for the human mind. Nor is it easy from the organizational point of view: policy design typically is sector-specific, whereas the impacts of technological change ripple through the whole society. In the governance models of today, such impacts, risks, and opportunities are not anticipated in a holistic manner. RTI-GPT provides an example and an accessible starting point for such efforts. The RTI methodology is designed to recognize societal value creation and related promising or harmful effects independently of sectoral boundaries and responsibilities. Thus, the discursive RTI-GPT can readily provide insights into boundary-crossing questions that are challenging to comprehensively answer from the perspective of existing “silos”. This feature, above all, should make it useful in recognizing issues that need attention, in facilitating discussion and policy planning between ministries, and in recognizing types of stakeholders that should be involved.

## What should technology developers pay attention to?

For technology developers, the main value of this report is not in treating it as a list of predictions, but as a guide to where future competitive advantage may emerge. Its real usefulness lies in showing where technological capability, standards, regulation, infrastructure, and shifting value networks may begin to reinforce one

another. The next wave of success is unlikely to come only from better technical performance. It will also come from recognizing early when a technology starts to change demand, reshape competition, and open space for new business models.

The report should therefore be used as a strategic navigation tool. It helps developers identify promising growth directions, test assumptions about where bottlenecks are moving, and see where new combinations of technologies may create openings before markets are fully formed. In practice, this means paying attention not only to the technology itself, but also to standardization, platform dependencies, component availability, regulation, and changes in the surrounding ecosystem.

The broader lesson is that technology success will increasingly depend on combining technical excellence with strategic flexibility. The strongest positions are likely to go to those who are early enough to learn, influence, and build capabilities, but pragmatic enough to adapt as markets, rules, prices, standards, best practices and networks evolve. Used in this way, the report is less a static forecast than a practical tool for spotting the next credible directions for technology-based growth.

## What should business decision makers pay attention to?

In a rapidly evolving technological and societal environment, business leaders must strengthen their ability to anticipate change and translate emerging insights into strategic action. This report serves as a navigation tool for organizations, helping leaders understand key shifts in the external environment and assess their relevance for business.

It provides a structured perspective on emerging technologies and their implications for future operating environments. By connecting long-term trends, technological progress, and weak signals, the report supports more informed choices under uncertainty and helps organizations prepare for the context in which they will operate.

In addition, the report offers insight into evolving value networks, customer needs, and broader societal conditions. Used as a basis for reflection and dialogue, it can help leaders prepare their organizations to remain resilient and competitive over the long term.

Effective leadership also requires continuous change management and capability development. Organizations need a clear strategic direction and a deliberate approach to building the capabilities required for future success. The report helps identify which capabilities should be strengthened or newly developed.

Finally, the report supports organizations in anticipating changes in value networks and customer needs. Future customers will operate in new societal and technological

contexts, with shifting expectations and demands. By understanding these changes early, organizations can better position themselves for long-term competitive advantage.

## What should citizens pay attention to?

For citizens, understanding technologies shaping the future can support more informed choices in work, daily life, and society. This report offers a way to make sense of these changes at a high level, helping individuals grasp what kinds of transformations may lie ahead and how today's choices connect to longerterm developments. For generally curious citizens, the report provides perspectives on how technology, work, and society may evolve over the coming decades.

From an individual perspective, particular attention should be paid to working life and skills development. As work becomes more flexible, distributed, and technologymediated, individuals increasingly need to reflect on what kinds of competencies they want to develop to remain relevant and resilient. For younger generations especially, the report offers context that can support education and career choices by illustrating how different futures may shape labor markets, roles, and required skills.

The report also highlights broader societal change, including how technologies often emerge first in leisure and everyday life before becoming embedded in work and social structures. Looking ahead, society twenty years from now may look very different from today, containing both risks and opportunities. The report does not present a single utopian or dystopian vision, but instead encourages awareness and active engagement. While technology has contributed to many challenges, it also offers tools to address them. By understanding these dynamics, citizens can move beyond passive concern and instead reflect on how individual choices, skills, and everyday actions can help shape the future society they wish to live in.

## Discontinuous transformations: the race between utopian and dystopian futures

The 2018 report in the series, *Societal Transformations 2018–2037*, introduced the concept of the sociotechnical regime. For each value-creation network, a plausible transformative structural shift was identified, contingent on significant advances in the anticipated technologies. A substantial share of these anticipated transformations appeared not only likely but appeared also to be discontinuous—that is, disruptive. In light of this, the report drew the following conclusion:

**The broad changes that are proven to be possible in this report and that extend to the foundations of the functioning of society raise the idea of the beginning of a new Kondratiev cycle and the old one encountering a crisis, which is normal for Kondratiev cycles. This report shows that the challenger regimes are maturing quickly and comparatively simultaneously, proceeding towards a potential, extensive transformation of the existing structures. Previous crises related to the beginning of a new cycle were linked to major wars, economic collapse, and reorganization of power structures at the global level.**

**(SOCIETAL TRANSFORMATIONS 2018–2037, LINTURI & KUUSI , P. 457)**

Over the past eight years, this view has only grown stronger, as can be seen from this report, and many of the geopolitical tensions intensified by these developments have already materialized in new wars. The collapse of industries and national economies now appears more plausible, while the rapidly growing power over infrastructural capabilities of global technology companies, geopolitical bloc formation, and the rapid advance of artificial intelligence and robotics are creating unprecedented turbulence in societies.

In light of the report's findings, however, we are still only at the beginning of these transformations, and the most profound disruptions still lie ahead. These changes will bring both threats and opportunities for all actors. The role of regulators is to open up opportunities while preventing threats from materializing. This will take place amongst major power struggles not only between states and blocks, but also with business conglomerates. The role of businesses and citizens is to remain agile and alert.

We have entered an era that would have seemed like pure science fiction not only to someone living a hundred years ago, but even to those who experienced the early years of the internet in 1990's. And it seems there are outcomes that seem dystopian but also views that can be called utopian. Slow responses will increase societal and individual risks and will probably lead to turmoil and failure in global competition for prosperity. Rapid accommodation to anticipated change will be required.

# Group 1 - Sensing, Measurement & Connectivity

## ART 01.001 Global Broadband Connectivity

### 1. ART extraction

**A) Primary capability:** A globally ubiquitous broadband internet service that can **deliver affordable, high-speed connectivity to any location on Earth**. This is achieved by orchestrating a hybrid network of LEO satellites, dense terrestrial 5G/6G cells, and local mesh nodes, so end-users experience reliable broadband regardless of geography or mobility. The system aims to **surmount coverage gaps and capacity constraints** of any single infrastructure by intelligently combining multiple technologies.

### B) Key sub-components/variants:

- **LEO satellite constellations for global coverage:** Swarms of low-Earth-orbit satellites (e.g., Starlink, OneWeb, Amazon's Kuiper) provide long-distance backhaul and reach sparsely populated or remote regions.
- **Terrestrial 5G/6G high-frequency networks:** Ultra-dense deployments of next-gen cellular (mmWave and Terahertz small cells, massive MIMO) in urban or high-demand areas to deliver multi-Gbps throughput locally. Future 6G research explores **THz links and advanced beamforming** for extreme data rates[1][2].
- **Community-operated mesh networks:** Local Wi-Fi/WiGig mesh nodes or micro-ISPs that use inexpensive equipment (often in unlicensed bands) to extend coverage in villages, rural communities, or within cities. These networks can route traffic peer-to-peer and leverage shared backhaul (including satellite links) to connect underserved users.
- **Reconfigurable Intelligent Surfaces (RIS):** Thin, electronically tunable metasurface panels on buildings or structures that **reflect or bend wireless signals** to fill dead zones and improve coverage without active repeaters. RIS can dynamically shape 5G/6G mmWave beams around obstacles[3][4], enhancing signal strength by tens of dB in trials.
- **Optical wireless links (Li-Fi and FSO):** Using light (e.g. LED-based Li-Fi or free-space lasers) to offload data in high-density indoor or point-to-point scenarios. Li-Fi, now standardized (IEEE 802.11bb-2023), can provide multi-Gbps wireless links via infrared/visible light, complementing radio Wi-Fi[5][6].
- **Adaptive, software-defined network control:** Intelligent management that auto-selects the best path (satellite vs. terrestrial vs. mesh) and handles user mobility, weather outages, or intermittent power. This includes software-defined networking (SDN) and adaptive compression/routing algorithms to maintain stable latency and throughput by shifting traffic among satellites, ground base stations, RIS-assisted links, or peer nodes as conditions change.
- **Rugged user terminals and small-cell access points:** End-user devices ranging from smartphone-integrated antennas to laptop-sized satellite terminals or solar-powered community Wi-Fi hubs. These automatically connect to the optimal available network and hide the underlying complexity from the user. Terminals must balance high performance with low power and cost, and new designs (e.g. phased-array flat panels) are emerging to meet these needs[7].

**C) Maturity indicators to look for:** Evidence of **working prototypes and commercial deployments** in each domain and successful integration among them. This includes: demonstration of multi-hop network "*hand-offs*" (e.g. a seamless switch from satellite to terrestrial connectivity), **field trials or pilots** offering broadband in remote areas via combined tech, and **standards or large-scale investments** that signal imminent scaling. Concrete signs would be: *operational services* (e.g. satellite broadband customers, mesh networks serving real communities), **proof-of-concept trials** for

new pieces like RIS or direct satellite-to-phone links, **multiple well-funded actors** (industry consortia, telcos, space companies) developing competing solutions, **performance milestones** (e.g. Gbps data rates at THz frequencies, RIS boosting signal by >10 dB in field, Li-Fi standard ratified), and **regulatory/standards adoption** (3GPP 5G NTN standards for satellite integration, IEEE Li-Fi standards, etc.). Evidence of *economies of scale* starting (cost/price reductions, volume production of equipment) and expanding use-cases (e.g. satellites used for cellular backhaul, or mesh networks adopted by governments) would indicate advancing maturity.

1. **Evidence (10–20 recent, reliable sources)**
2. **Starlink LEO constellation performance – Richter et al., IFIP Networking (2025):** *Peer-reviewed measurement study (Potsdam Univ.) – Published 2025.*  
Using ~2.5 years of data (2022–2024), this study shows **Starlink’s large LEO network** achieving median latencies ~100–150 ms (with best-case ~80 ms) and improving over time as more satellites & ground stations were added[8]. It notes a **bimodal latency distribution** (some links <100 ms, others ~150–250 ms) and non-trivial packet loss (e.g. >10% in Germany) due to network variability[9]. *This demonstrates the plausibility of global satellite broadband – latencies nearing terrestrial broadband and real deployments serving users – while also highlighting remaining challenges (performance inconsistency, need for more ground infrastructure) that ongoing R&D is addressing.*
3. **100 Gb/s THz wireless link demo – Keysight/NPL/Surrey (U.K., 04/2023):** *Industry lab press release (Keysight Technologies) – April 2023.*  
A collaboration between Keysight, the UK National Physical Lab, and University of Surrey achieved the **U.K.’s first >100 Gb/s wireless link at 300 GHz** (sub-THz band) using a 6G testbed[1]. The prototype used advanced 32/64-QAM modulation and precision front-ends to establish a stable data connection in the 300 GHz band[2]. *This result confirms the feasibility of the ultra-high-frequency wireless component (mmWave-to-THz) needed for future 6G: multi-Gbps throughput and low latency over short ranges. It addresses a key technical pillar (massive capacity) and indicates fast-paced progress towards 6G-grade backhaul and access links.*
4. **RIS-aided wireless field trials – Pei et al., preprint (08/2023):** *Experimental research preprint (X. Pei et al.) – Aug 2023.*  
Researchers built and tested a **Reconfigurable Intelligent Surface (RIS)** prototype in real environments for 5G. In indoor trials at 5.8 GHz, the passive RIS panel provided **+10–20 dB signal power gain** to a receiver, and even **+35 dB gain outdoors** by reflecting a base station’s signal[10]. However, when integrated into a live 5G network (2.6 GHz band), the RIS yielded a smaller 4–7 dB improvement in indoor cell coverage[11]. *These results validate that RIS devices can substantially boost wireless coverage and throughput, though effectiveness depends on deployment scenario. It marks a solved “lab to field” step for metasurfaces, a once-theoretical technology now demonstrated in office, corridor, and outdoor settings.*
5. **RIS technology survey and roadmap – Yuan et al., China Mobile (ZTE Communications, 03/2022):** *Industry research report – March 2022.*  
Experts from China Mobile Research Institute review **progress in reconfigurable intelligent surfaces over the past 2–3 years**, covering academic advances (metamaterials designs, channel modeling, joint BS-RIS optimization) and industry developments (field trials, control protocols, standardization)[12]. They discuss realistic performance targets, compare RIS with other coverage solutions, and propose a timeline toward **RIS standardization for 6G**. *This authoritative roadmap shows that major telecom stakeholders are actively investigating RIS as*

*a relay/coverage technology, with standard bodies and operators planning for its integration into beyond-5G networks. The presence of such a roadmap underscores that RIS has moved from theory into the engineering discussion needed for commercialization.*

6. **Community mesh networks scaling up – Internet Society report (10/2022):** *Technical report (Internet Society & Connect Humanity) – Oct 2022.*

This report documents case studies of community-owned connectivity. For example, a mesh Wi-Fi network in rural Thailand (Net2Home) operates **260+ wireless mesh nodes across 24 villages**, serving ~1,200 subscribers with affordable internet[13]. Another initiative developed the open-source “**LibreRouter**” – a low-cost mesh router hardware – to cut deployment costs and leverage free spectrum, supported by grants[14]. *These cases prove the viability of community-operated mesh networks as part of the global connectivity puzzle. They have demonstrated technical and financial feasibility (hundreds of nodes, thousands of users) in underserved areas, indicating that mesh networking can complement satellites and cellular in the “last mile” for remote communities.*

7. **Space-based 5G to smartphones – Vodafone & AST SpaceMobile (press release, 09/2023):** *Operator press release (Vodafone) – Sep 2023.*

In September 2023, Vodafone and AST SpaceMobile successfully placed a **5G voice call from a standard Samsung smartphone** to a satellite in LEO (BlueWalker-3)[15]. They also achieved a downlink data session ~14 Mb/s to the phone from space[16]. This world-first demonstration of direct satellite-to-handset 5G was quickly followed by plans to deploy five larger “BlueBird” commercial satellites in 2024. Vodafone notes it will also use LEO satellites to **backhaul traffic between remote cell sites and core networks**[17]. *This is a pivotal proof-of-concept for integrating non-terrestrial networks: it shows that existing 5G devices can connect via satellite with acceptable performance. It rules out fundamental feasibility concerns and indicates multiple major players (mobile operators, satellite startups) moving toward commercial “cell towers in the sky” for continuous global coverage.*

8. **Li-Fi standardization – IEEE 802.11bb Light Communications (ratified 06/2023):** *Standards body publication/news – June 2023.*

IEEE approved the 802.11bb amendment, creating the first global Li-Fi networking standard. It defines MAC/PHY changes to enable **bidirectional wireless networking over infrared/visible light** with rates from a minimum 10 Mb/s up to **9.6 Gb/s** (comparable to Wi-Fi 6)[5]. The Li-Fi spec operates in 800–1000 nm optical band and is designed to integrate with existing Wi-Fi ecosystems[6]. Industry groups (pureLiFi, Fraunhofer HHI) lauded this standard for allowing interoperable Li-Fi products that complement RF Wi-Fi – adding capacity where radio spectrum is crowded or security needs are high[18][19]. *This milestone shows that optical wireless tech has matured from experiments to standardized solutions. Early Li-Fi products (gigabit-class light modems for laptops and industrial use) are now being built to this standard, indicating the technology’s readiness to join the global connectivity toolkit, especially for specialized environments (offices, airplanes, secure facilities).*

9. **Amazon’s Project Kuiper (Amazon Leo) prototype deployment – GeekWire (11/2025):** *Tech news report (Alan Boyle, GeekWire) – Nov 2025.*

Amazon’s satellite broadband constellation (recently rebranded “**Amazon Leo**”) entered its pilot deployment phase in late 2025. They began shipping **production-grade user terminals** to select enterprise customers, after years of R&D[20]. The top-tier service “Leo Ultra” promises ~1 Gbps download and 400 Mbps upload, using a 20×30 inch phased-array antenna[21]. Two smaller terminal types will offer 100 Mbps (7" antenna) and 400 Mbps (11" antenna) for

standard users[22]. By Nov 2025 Amazon had ~153 satellites in orbit and partnered with airlines (JetBlue for in-flight Wi-Fi) and telecom operators (Verizon, Vodafone, etc.) to integrate the service[23][24]. *This demonstrates multiple well-capitalized actors racing into LEO broadband. Amazon's entry – with innovative low-cost antennas and cloud integration (direct AWS access) – underscores that the satellite component is moving rapidly toward scaled commercial offerings, driving competition, and likely lowering costs. The involvement of telcos and large clients also suggests growing confidence in satellite-terrestrial interoperability.*

#### 10. **5G-standard satellite integration – 3GPP Release 17 NTN (specs completed 03/2022):**

*Standards working group article (3GPP/GSOA) – July 2022.*

3GPP Release 17 introduced formal support for **Non-Terrestrial Networks (NTN)**. The specification (frozen in March 2022) allows standard 5G New Radio to run over satellites in low Earth orbit, in regular mobile bands, to **serve handheld devices globally**[25]. It also added satellite support for NB-IoT and LTE-M, enabling massive IoT use-cases via satellite. The report notes that with Rel-17 complete, the first commercial devices for satellite-direct 5G were expected by ~2024[26]. Work in Release 18+ is extending this to higher frequencies and mobility (e.g. satellite links to planes, ships, and integrating building-mounted terminals)[27]. *The presence of NTN in 5G standards is strong evidence of technical feasibility and imminent deployment: it means the global wireless industry has agreed on how to incorporate satellites for coverage and continuity. This pushes the concept beyond individual demos to a widely-adopted framework, smoothing the path for devices and networks to support multi-network handoff (e.g. phones using satellite when out of cell range).*

#### 11. **Metasurface coverage enhancement trial – NTT DoCoMo (press release, 01/2023):**

*Operator R&D press release – Jan 30, 2023.*

Japan's NTT DoCoMo announced a successful field trial using a **film-based transmissive metasurface (RIS) on a building window** to bend indoor 28 GHz signals down to street level outside. Conducted Oct–Nov 2022, the test showed that attaching a transparent metasurface film to the interior of office windows can **redirect mmWave 5G signals to fill coverage shadows at the foot of the building**, greatly improving throughput there[28][29]. The metasurface did not affect aesthetics or sub-6 GHz signals and requires no power. *This is a practical demonstration that reconfigurable surfaces can solve real deployment pain points – in this case, extending millimeter-wave coverage around obstacles without additional base stations. It lends plausibility to the ART's claim that simple, passive deployments (on windows, walls, etc.) can dramatically boost network efficiency and coverage in high-frequency systems.*

#### 12. **Maturity score (1–7) and reasoning**

**Final Score: 6 (Early Commercial).** The evidence suggests that **global broadband connectivity** as a unified, multi-technology concept is on the cusp of broad commercialization. *Key components have graduated from proof-of-concept into active use, and multiple industry giants are investing to scale them, although full seamless integration is still emerging.* Below, we map the findings to the rubric criteria:

- **Why not lower (levels 1–4)?** The core scientific feasibility was established long ago (satellite internet and wireless broadband are well-proven), and we now see much more than isolated lab demos. *There are working prototypes and commercial services (Starlink, OneWeb, 5G mmWave networks, community meshes) – satisfying and exceeding level 3.* In fact, Starlink's deployment of ~4,000 satellites and serving real customers demonstrates a solved prototype-to-product transition. Standards development (e.g. 3GPP NTN in 2022) and large-scale trials

(AST's satellite 5G calls in 2023) show that **previously blocking problems (latency, integration of sky and ground networks)** are being overcome – fulfilling the “Proof of Concept” threshold (level 4). Moreover, **clear advantages over legacy solutions** are evident: e.g. LEO satellites deliver <100 ms latency vs. ~600 ms on old GEO sats, and Terragraph mesh can provide fiber-like multi-Gbps in areas fiber can't reach[30][31]. These breakthroughs, plus active field testing of RIS and Li-Fi, collectively *rule out the lower maturity levels 1–4*. The technology family is no longer just theoretical or confined to labs – it is partially operational and steadily improving.

- **Why not fully highest (level 7)?** Not all pieces have reached mature market competition yet. While **satellite broadband is at level 6/7** (Starlink has millions of users and competitors are entering[23][24]), other elements like **RIS and 6G** are earlier in the pipeline (mostly at demo stage, not deployed at scale). The **integration of networks is not yet seamless or ubiquitous** – e.g. direct satellite-to-phone links only just hit their first voice call in 2023[15], and software to dynamically juggle traffic across satellites/terrestrial/mesh is still in development (initial standards exist, but few real deployments). In rubric terms, the overall “Global Connectivity” bundle has *pockets at level 7 and others around level 3–5*, so it hasn't uniformly achieved level 7's hallmarks (widespread competing products and self-sustaining market growth across all sub-techs). **Key missing evidence for level 7** includes: truly global, **affordable coverage at scale (billions of users)**, and fully integrated service offerings where a user's device roams between satellite, cellular, and local mesh as transparently as between cellular towers. Also, **cost and capacity challenges** remain before we declare the bottleneck solved: for instance, the capital expense for complete coverage is still enormous, and technologies like RIS or Li-Fi have not yet been mass-produced to drive down cost.
- **Sub-component breakdown:** To illustrate the mixed maturity, we assign sub-scores:
  - *LEO satellite broadband: 6–7.* Starlink and OneWeb are delivering service (Starlink's latency & throughput now rival basic terrestrial broadband[8]). Multiple funded competitors (Amazon, Telesat) are racing to deploy, matching rubric level 7's competition and rising demand – though global affordability and some regulatory aspects are still in progress.
  - *Terrestrial 5G (mmWave) networks: 6.* 5G infrastructure is widely deployed (billions of users covered), and mmWave small cells exist commercially (Verizon's 5G UW, etc.), albeit not yet pervasive. The tech works (multi-Gbps demos[32]) but dense build-out is ongoing. 6G research (THz links) is at lab prototype stage[33], roughly level 3, but since 6G will largely extend 5G capabilities, the current cellular system already provides a functional baseline.
  - *Community mesh networks: 4–5.* Proven in niche deployments (hundreds of node networks[13]), with support from NGOs and even some governments. Not yet a mass-market or corporate product, but practical know-how exists (open-source hardware, financing models[14]). This segment is moving past PoC into scalable pilots, but needs more funding to reach level 6.
  - *Reconfigurable Intelligent Surfaces: 3.* Strong experimental success (20–35 dB gains in trials[4], transparent films tested on real buildings[34]). RIS are not commercial yet; industry roadmaps target 6G for deployment. Thus RIS are at “functional prototype demonstrated” stage.

- *Li-Fi (optical wireless): 4.* Now standardized and early products exist (e.g. pureLiFi's Light Antenna module). It's moving toward commercial integration (some defense and industrial Li-Fi systems are already sold), but mainstream adoption and large-volume production are just beginning post-2023 standard, keeping it below level 6 for now.
- *Network integration & orchestration: 4.* The concept of a seamless global network is proven in parts (standardized APIs in 5G core for satellite, first satellite-cell handovers done). Some startups (AST, Lynk) are essentially creating “**space cellular**” networks, and 3GPP Rel-17 ensures regular phones can use them[25][26]. Still, truly dynamic multi-network routing (satellite ↔ mesh ↔ cellular on the fly) remains in early implementation. We've seen proofs (e.g. Vodafone using LEO backhaul for remote towers[17]), but not yet at scale or fully automated globally.

Given these facets, the **bundle's overall maturity is an average** of its parts rather than led solely by the most advanced element. Satellites and 5G push the score higher, while nascent tech (RIS, 6G) pull it down. **Aggregating these, we arrive at roughly a 5–6.** We choose **6** to reflect that a functioning albeit partial version of global broadband connectivity **is already in customer hands today** (millions benefitting from satellite internet and 5G), and the pace of progress is high. The “full vision” (truly ubiquitous, efficient, and integrated coverage) will likely materialize in the next few years as these components converge. In summary, the concept is in the **early commercial stage** – no longer speculative, with active deployment and rapid improvement underway, but not yet at the mature, ubiquitously adopted stage that would merit a 7.

## ART 01.002 Ultra Low Latency Networks

**Primary capability** – Enables **near-instantaneous, deterministic network response** (end-to-end delays of only a few milliseconds) for distributed systems. This allows remote sensing, computing, and actuation to operate with **minimal lag and jitter**, approaching the reactivity of local (on-device) interactions. The goal is to support time-critical applications (e.g. industrial control, autonomous systems, collaborative robots, AR/VR) by guaranteeing bounded low latency across the network.

**Key sub-components or variants** – Achieving ultra-low latency networking requires progress on multiple fronts working in unison: - **Edge computing infrastructure:** Dense deployment of computing nodes closer to end-users and devices (metro or base station level) to shrink physical distance and propagation delay. Cloud providers and telcos are partnering to host compute at the network edge, exposing services with single-digit ms latencies. -

**Deterministic networking protocols (wired and wireless):** New standards like IEEE Time-Sensitive Networking (TSN) for Ethernet and 5G URLLC for wireless aim to provide guaranteed delivery within tight deadlines. This includes scheduling mechanisms, priority traffic lanes, and time slotting to avoid unpredictable queueing delays. - **Precise time synchronization:** Network elements use common time references (via IEEE 1588 PTP or GPS-disciplined clocks) to coordinate transmissions and processing, so that packets and tasks can be

scheduled with microsecond-level accuracy and avoid collisions or variability. - **Real-time network software stacks:** From NIC hardware up through OS kernels and application frameworks, the stack is optimized for low latency determinism. Examples include kernel bypass techniques, optimized interrupt handling, and real-time OS or container scheduling to ensure processing deadlines. - **Network slicing and QoS control:** The ability to carve out dedicated low-latency “slices” in 5G/6G networks or to prioritize time-critical flows in IP networks (DiffServ, Segment Routing, etc.), so that high-priority traffic (e.g. control signals) always preempts less critical data. - **Specialized hardware and spectrum:** Use of high-bandwidth channels (e.g. mmWave or future terahertz) and advanced physical-layer techniques (MIMO, diversity, coding optimized for short packets) to reduce transmission time. Custom silicon (switches with scheduling hardware, FPGAs for in-network processing) and high-precision oscillators are employed to meet tight timing requirements. - **Integration of wired and wireless deterministic networks:** Convergence of Ethernet TSN with 5G/6G wireless (e.g. 5G acting as a TSN bridge) to extend low-latency guarantees over the air. This hybrid ensures factory or vehicular networks can maintain hard real-time performance even when part of the link is wireless.

**Maturity indicators** – Evidence of progress toward ultra-low latency networks would include: - **Working prototypes and field trials:** e.g. demonstrations of sub-5 ms end-to-end latency in real-world scenarios (industrial robot control, remote driving, cloud VR streaming) under realistic loads. Successful PoCs showing deterministic latency and high reliability (e.g. >99.999% on-time delivery) would validate feasibility. - **Standards and interoperability tests:** Completion of relevant standards (5G URLLC in 3GPP Releases, IEEE TSN profiles like 60802 for industrial use) and multi-vendor interoperability demos. Regulatory certifications for safety-critical use (e.g. in energy or transportation) would signal technical maturity. - **Commercial services and hardware availability:** Low-latency edge computing services available in multiple regions; networking gear (switches, NICs, 5G modems) advertising TSN/URLLC capabilities and being deployed in pilot programs. Early adoption in sectors like manufacturing (private 5G+TSN installations) or telecom (edge cloud offerings) with performance reports. - **Investment and competition:** Significant R&D funding and involvement by major industry players (global telcos, cloud giants, industrial automation firms, chipset manufacturers). Multiple consortiums and alliances (e.g. 5G-ACIA for industrial 5G) working on solutions, indicating a competitive race to bring products to market. - **Scaling and cost trends:** Evidence that deployments are ramping up (even if in niche areas) – for example, increasing number of edge data centers built, or growth in sales of TSN-enabled devices. Signs that economies of scale are improving (cost per edge node or per device decreasing) and that energy/cooling challenges for dense edge nodes are being addressed would suggest approaching commercial viability.

## 2. Evidence (10–20 recent, reliable sources)

- **Wang et al. – “Ultra-Low Latency Wireless Communications for Deterministic Networking: A Cross-Layer Approach”** (IEEE ICC 2022 conference paper, 05/2022)[1][2]. *Provides a theoretical framework for achieving near-zero packet delay violation in wireless IIoT networks. It proves that strictly bounded latencies require exploiting frequency diversity, multi-antenna MIMO, and cooperative relays to overcome fading; under causal (real-time) channel conditions zero packet loss under hard deadlines is impossible with finite power, but with added diversity and scheduling foresight, ultra-reliable low-latency transmission becomes feasible. This*

indicates the physical-layer and MAC-layer innovations needed for plausibility of deterministic 5G/6G links.

- **Zhao et al. – “Latency Analysis and Field Trial for 5G NR”** (IEEE BMSB conference 2022, 06/2022)[3]. Describes new 5G features introduced to reduce latency (such as mini-slot transmission, enhanced scheduling) and reports results from a field trial of 5G New Radio latency. The trial demonstrated that under specific configurations, 5G can meet the latency targets for enhanced Mobile Broadband (eMBB) services (on the order of a few milliseconds). The authors also identify remaining gaps and suggest optimizations needed to reach the far stricter Ultra-Reliable Low-Latency Communication (URLLC) goals, underscoring that while 5G has made progress, further R&D is required for the most demanding applications.
- **Maghsoudnia et al. – “Ultra-Reliable Low-Latency in 5G: A Close Reality or a Distant Goal?”** (ACM HotNets workshop paper, 11/2024)[4][5]. A system-level analysis from EPFL and collaborators that evaluates the real-world status of 5G URLLC. It notes that several years into 5G deployments, achieving the promised 1 ms latency and high “five 9s” reliability in practice remains elusive, due to bottlenecks across software, hardware, and protocol layers. While some prototype implementations exist, none yet meet all latency/reliability specs simultaneously[5]. The paper outlines how 6G research is pursuing even stricter targets (0.1 ms one-way) and argues that only a holistic redesign (e.g. using application-specific hardware for many protocol layers[6]) could meet URLLC requirements. This highlights both the plausibility of ultra-low latency (with redesign) and that maturity is still at the experimental stage, requiring significant engineering to move beyond theory.
- **AWS (J. Naylor) – “Lower access latency for your apps with AWS Wavelength and our telco partners”** (AWS Industries Blog, 10/2024)[7]. Reports on measurements of a production edge computing service (AWS Wavelength) deployed inside 5G networks. It shows that placing compute and storage at the 5G edge can reduce round-trip latency by ~8–12 ms compared to routing to a distant cloud region[7]. For example, in one test a user’s ping to an AWS Region was ~48 ms, whereas to the nearest Wavelength Zone it was ~36 ms – a significant improvement purely from proximity. This confirms the feasibility of cutting network lag via edge infrastructure, and demonstrates a commercial offering already providing single-digit-ms improvements for mobile applications (e.g. cloud gaming, AR). It also notes factors like backhaul design and device connection (5G vs WiFi) that influence achieved latency.
- **Industrial Ethernet Book – “2023 Time-Sensitive Networking Technology Update”** (Trade magazine report, 03/2023)[8][9]. Summarizes input from industry experts on the status of IEEE TSN for real-time Ethernet. It highlights that many semiconductor companies are now integrating TSN capabilities into chips (switches and network controllers), and industrial consortiums are developing standardized profiles (e.g. IEEE/IEC 60802)[8]. However, the report notes that as of 2023, these new TSN-enabled components still need to be incorporated into final products by device vendors and go through testing/certification before widespread use. Middleware and industrial protocols (like Profinet, OPC UA) are each following their own roadmaps to adopt TSN[10]. This indicates that the building blocks for deterministic, low-latency wired networks are emerging (hardware and standards), but full market adoption is still in progress pending integration and proof of reliability at scale. It underscores active work and growing confidence in TSN as a cornerstone for ultra-low latency in factories.
- **Cumucore (Qualcomm & partners) – “TSN over 5G demonstration using commercial components”** (Industry blog, 08/2025)[11][12]. Announces the first public demonstration of Time-Sensitive Networking over a live 5G link using off-the-shelf hardware. In August 2025, Cumucore, Qualcomm, a Finnish operator (DNA) and others showed that a 5G Standalone network could transport TSN traffic with full synchronization and bounded latency. This demo,

involving use cases like coordinated welding robots, proved that wireless 5G can act as a seamless extension of deterministic Ethernet[11]. They report that the solution is moving from proof-of-concept toward practical deployment, with ongoing work to refine timing synchronization (Grandmaster clock integration) and scalability[12]. This is strong evidence of plausibility – it validates that sub-ms-level synchronization and low jitter can be maintained wirelessly – and it marks a maturity milestone: by 2025, wireless TSN is transitioning from lab demo to initial field integration, a step toward commercialization in high-value industrial scenarios.

- **Haque et al. – “A Comprehensive Survey of 5G URLLC and Challenges in the 6G Era”** (Preprint, arXiv Aug 2025)[13][14]. An exhaustive survey reviewing over 280 papers on URLLC. It emphasizes the challenge of achieving <1 ms end-to-end latency in real networks, noting that while 1 ms can be met at the radio link level in small local setups, ensuring that across a wide-area network (with processing, routing, queuing delays) is extremely difficult[13]. The authors explain the fundamental latency-reliability trade-off: URLLC needs very short packets and time slots to cut delay, but this limits error-correcting capabilities, so new techniques are needed to maintain 99.999% reliability within those tight latency budgets[14]. The survey also points out that much URLLC research remains theoretical or simulation-based, with relatively few real-world implementations reported. This source underscores that scientific interest and understanding are high (TRL1–2 achieved), but also that meeting the full URLLC spec in practice is still an open problem, requiring innovations in protocol design, cross-layer optimization, and perhaps AI-driven control to juggle the competing demands.
- **Kornacki et al. – “Meeting Industrial 5G Requirements for High Uplink Throughput and Low Control Latency in UGV Scenarios”** (Applied Sciences journal, 06/2025)[15]. Presents results from a 5G SA testbed at Gdańsk University of Technology controlling an Unmanned Ground Vehicle (UGV) with LiDAR. The study tweaked 5G base station parameters to optimize for an unusual combo: high uplink throughput (for LiDAR video) and ultra-low downlink latency (for control commands). It reports that by configuring CSI feedback, timing signals (TRS/SSB), and scheduling request intervals, the team achieved stable high-bandwidth uplink while keeping control-plane latency within the strict 3GPP industrial limits[15]. In good radio conditions, the best configurations met the sub-10 ms control latency and reliability needed for real-time remote driving, even with heavy sensor data flowing. This demonstrates a proof-of-concept system meeting URLLC-like specs: it shows that today’s 5G can be tuned to deliver industrial-grade performance on a small scale, supporting the feasibility of remote-operated vehicles and similar tactile internet applications once the network is properly optimized.
- **Alves et al. – “Beyond 5G URLLC Evolution: New Service Modes and Practical Considerations”** (ITU Journal: Future and Evolving Tech, 12/2022)[16][17]. An authoritative article by researchers from Nokia Bell Labs and Univ. of Oulu reviewing two advanced URLLC testbeds (in Finland and South Korea) and proposing future URLLC variants. It observes that current 5G URLLC has inherent limitations and likely cannot support emerging applications with even stricter needs (e.g. sub-millisecond latency, higher data rates, and device densities)[16]. The authors introduce concepts of Broadband URLLC, Scalable URLLC, and Extreme URLLC, which would extend 5G’s capabilities to cover these new extremes. They identify key enabling technologies for each (such as smarter scheduling, XR communication techniques, or AI for network optimization) and report practical lessons learned from their test networks[17]. This source highlights that industry and academia are actively pushing beyond 5G’s baseline, acknowledging that while 5G URLLC is on the path to deployment, truly ubiquitous ultra-low latency with higher reliability may only be realized with these next-generation improvements (e.g. 6G around 2030). It reinforces that the vision is plausible but will be an evolving target over the next decade, not a solved problem today.

(Additional evidence consulted includes NIST and Keysight reports on wireless TSN and standards progress, and demonstrations of remote surgery and VR over 5G, which further support these findings but are omitted for brevity.)

### 3. Maturity score (1–7) and reasoning

#### Final maturity score: 5 (Out of 7).

**Justification** – Ultra-low latency networking is **beyond the pure research phase** and has progressed into working prototypes and early services, but it is **not yet a widely deployed commodity**. Level 5 on the rubric corresponds to multiple well-funded actors developing production prototypes post-PoC, which is exactly the current situation: - **Exceeds Level 3/4:** We have more than lab demos – *functional PoCs* have been demonstrated meeting key requirements. For instance, the Cumucore/Qualcomm 2025 demo showed real 5G wireless TSN delivering deterministic low latency in an industrial scenario[11], and AWS offers an edge cloud service cutting latency by an order of magnitude for mobile apps[7]. These indicate that the core technical blockers (scheduling, edge placement, sync) *can* be solved in practice, ruling out the lower “proof of concept not yet done” levels. The 5G URLLC field trial in 2022 similarly proved that under tuned conditions, 5G can hit its latency targets[3]. This progress satisfies Level 4 (prototype viability demonstrated) and goes beyond it. - **Rationale for Level 5:** There is now **intense competition and investment** to productize these capabilities. Major telecom vendors (Ericsson, Nokia, Qualcomm), cloud companies (Amazon, Microsoft), and industry consortia (5G-ACIA, etc.) are all racing to deliver ultra-low latency solutions. Multiple prototypes are in late-stage development or early deployment – e.g. private 5G networks with TSN are being rolled out in trial industrial sites, and 5G Advanced and 6G research explicitly targets <1 ms latency[4][16]. The ecosystem has the hallmarks of Level 5: well-capitalized actors, clear commercial motivation, and rapid progress in standards and pilots (for example, 3GPP Release 16/17 adding deterministic features and companies aligning hardware to those standards[16]). - **Not yet Level 6:** However, **full commercial maturity has not been reached** – we do not yet see broad customer deliveries of “URLLC as a service” or pervasive ultra-low-latency networks in daily use. Current 5G networks largely fall short of the strictest latency/reliability goals[4], and the technologies are still in bespoke deployments or trials rather than mass production. Challenges around coverage (edge node proximity), cost, and integration are still being worked out. Thus, the technology isn’t at scale with economies of scale driving down price, which is what Level 6 would require. Reliability and safety certification in real operations (e.g. for autonomous driving or remote surgery) are in progress, not done. - **What’s missing for Level 6:** To reach the next level, we would need to see **routine delivery of ultra-low latency capabilities to end-users**. That means telecom operators offering guaranteed-ms latency slices as a product in many regions, industrial suppliers shipping turnkey low-latency wireless control systems, and a growing base of end devices and applications using them. Evidence such as large orders or deployments (hundreds of edge sites serving thousands of customers), multi-vendor product offerings, and falling costs would be expected. Also, regulatory frameworks (for reliability, data handling in critical latency services) would likely be in place. Those elements are only starting to form now.

**Sub-component breakdown:** The overall score of 5 is an **aggregate** reflecting different parts of this technology bundle: - *Edge cloud infrastructure:* **6** – Cloud/telco edge services are already deployed (e.g. AWS Wavelength, Azure Edge Zones) and increasingly adopted, demonstrating growing scale[7]. - *Wired deterministic networking (TSN):* **5** – Standards are

finalized and first products available; industry trials underway (e.g. TSN in automotive and manufacturing)[8]. Needs broader adoption but technically at prototype/early product stage.

- *Wireless URLLC (5G/6G)*: **3–4** – The concept is proven in labs (sub-ms radio frames, special scheduling) and some field demos, but current 5G networks do **not** yet meet full URLLC in practice[4]. It's at advanced R&D/prototype phase, with 6G work aiming to close the gaps.
- *Integration (5G + TSN + edge)*: **4** – Recent PoCs show it works in limited settings[11], but comprehensive commercial solutions (combining all elements reliably) are still in pilot stage.

These factors combined justify a **score ~5**. We chose **5 (competing development and imminent prototyping)** rather than 4, because many pieces have graduated from concept to implementation and are being aggressively developed concurrently. The functionality across sub-components contributes to one value proposition (real-time networked computing), so we consider the **system as a whole**. In this case the bundled capability is only as strong as its weakest link – wireless URLLC – which lags behind edge compute and TSN. But given the **high industry momentum** and the fact that partial services are already live, a mid-to-high maturity (5) best captures where Ultra-Low Latency Networks stand today, with the **caveat** that full performance is a couple of steps from wide rollout.

## ART 01.003 Edge AI for Sensor Data

### 1. ART extraction

- **Primary capability:** Enabling *real-time, on-site AI processing of sensor data* at the point of capture. This allows immediate interpretation of raw signals and autonomous decision-making without relying on cloud connectivity. It dramatically reduces bandwidth usage and latency by filtering, compressing, or analyzing data locally[1][2], improving responsiveness and privacy.

- **Key sub-components/variants:**

- *Ultra-low-power edge AI hardware:* Specialized microcontroller units (MCUs), DSPs, or NPUs integrated in sensors or nearby modules, capable of running neural networks within tight energy and memory budgets[3][4]. Some approaches embed processing *in-sensor* (at the pixel or transducer level) versus *near-sensor* chips adjacent to the sensor[5][6].

- *Compact ML models (TinyML):* Neural networks optimized via quantization, pruning, and efficient architectures to fit on resource-constrained devices while maintaining accuracy[7][8]. Examples include tiny vision models for cameras or lightweight audio/vibration models for anomaly detection.

- *Robust sensor fusion & adaptation:* Algorithms combining multiple sensor modalities (video, audio, inertial, etc.) to improve reliability in noisy or adverse conditions. Techniques like self-calibration and on-device uncertainty quantification are used so the system can “gracefully degrade” when data is partial or corrupted[9][10].

- *Distributed edge networking:* Edge AI devices typically connect via local networks, performing autonomously when offline and syncing periodically. Standard dashboards or mobile apps allow humans to view sensor insights and adjust settings. Over-the-air updates and federated learning can be used to retrain or update models using aggregated field data, improving performance over time.

- *Application-specific variants:* Smart cameras with on-board object or event detection, intelligent microphones for keyword spotting or equipment noise analysis, wearables with built-in health anomaly detection, and industrial controllers with vibration/temperature analytics are all examples under this technology bundle. Each may use different model types but share the paradigm of on-site AI inference.

- **Maturity indicators:** Evidence would include **field trials and deployments** (e.g. sensors with embedded AI used in real farms, factories, etc.), **commercial products shipping** (smart sensors or devices with advertised on-board AI features), **multiple industry players** (sensor and chip makers, IoT platforms, consortia investing in edge AI), and **performance benchmarks** showing clear advantages over cloud-only solutions (e.g. reduced latency,

bandwidth, or improved reliability under real-world conditions). Signs like standard toolchains (TinyML frameworks, model libraries), *well-funded competition* among companies, and increasing adoption across sectors would also indicate rising maturity. Demonstrable **robustness in harsh environments** (dust, low-light, etc.) and compliance with safety/security requirements in deployments would further validate the technology's readiness.

## 2. Evidence (10–20 recent, reliable sources)

- **“Edge AI: A survey” – R. Singh, S. S. Gill – *Internet of Things and Cyber-Physical Systems* (peer-reviewed) – 2023.** *Comprehensive open-access survey of Edge AI.* It presents a “future blueprint” for deploying AI on edge devices, covering model optimizations for resource-constrained hardware and examining **standardization and performance benchmarks** for Edge AI environments[11][12]. It also identifies open challenges (latency, energy, tool integration) and trends, indicating broad academic and industry interest in making edge AI practical. This underscores that the field has matured to the point of formal surveys and recognized best practices.
- **“Deploying TinyML for energy-efficient object detection...” – Ch. M. Bhushan et al. – *Scientific Reports* (Nature, peer-reviewed) – Dec 2025.** *Demonstrates a real-time vision model on a microcontroller (“TinyML”).* The authors deploy a quantized MobileNetV2 on a 1 MB flash / 256 KB RAM MCU to perform person detection from a camera[3][13]. They achieved on-device inference in 3.5–15 ms per frame with only 10–22 mJ energy per inference, while maintaining **85%+ accuracy**[8]. This *lab-validated prototype* shows that non-trivial AI tasks (e.g. detecting people via a Visual Wake Words dataset) can run within millisecond latency and milliwatt energy on cheap hardware – a key feasibility proof for edge AI’s responsiveness and low-power operation.
- **“Edge intelligence through in-sensor and near-sensor computing for AIoT” – Y. Baek et al. – *npj Unconventional Computing* (Nature, perspective) – Oct 2025.** *Technical roadmap and perspective on moving computation into sensors.* It surveys emerging device and circuit innovations that turn sensors from passive data collectors into active computing nodes. For instance, it highlights **in-pixel and near-sensor processing** that eliminate costly data transfer and ADC steps[5][6]. The article notes that *bio-inspired, event-driven sensors* (neuromorphic vision, silicon cochlea, etc.) can perform **event detection and filtering on-device**, drastically reducing power and latency[14][15]. It also discusses challenges like device variability and the need for new architectures[16]. This evidence reinforces the plausibility of the ART, showing a clear scientific path for integrating AI logic at the sensor level and acknowledging what engineering hurdles remain.
- **“Resource-efficient Edge AI solution for predictive maintenance” – V. Artiushenko et al. – *Procedia Computer Science* (open-access conference) – 2024.** *Describes a prototype tool-condition monitoring system using Edge AI.* The paper presents a **low-cost hardware setup** where a microprocessor at a machine tool runs multiple ML models to monitor milling tool wear in real time[17]. Four classical ML models and one deep learning model were deployed on a “low-performance edge device” and validated during actual milling operations[18]. This prototype achieved the necessary functionality (detecting tool wear) locally, and the authors discuss integration challenges and future improvements. It is a concrete example of Edge AI enabling **real-time industrial monitoring** on the factory floor, confirming the ART’s practical value (latency reduction, autonomy) in manufacturing settings.

- **“Resource-Constrained Edge AI for Real-Time Pest Detection in Chili Fields” – H. Chung et al. – Agriculture (MDPI, peer-reviewed) – Feb 2026.** *Reports a field-deployable edge AI system for smart farming.* The team built an **on-premise IoT pipeline** using AI-Thinker ESP32-CAM modules (“sticks”) as smart camera sensors and a Raspberry Pi 5 as a local edge server[4]. They developed a two-stage model (tiny YOLOv8 for leaf detection plus ResNet-18 classifier) to identify crop diseases on chili pepper leaves. To handle patchy farm connectivity, the system uses dual protocols (HTTP for images, MQTT for alerts) with an offline buffer/recovery mechanism[19][20]. In tests, it achieved an end-to-end detection and alert latency of **0.86 s** and cut computation by >60% versus heavier models with minimal accuracy loss[21]. This is strong evidence of an **autonomous, multi-device edge AI network operating in a real-world, harsh environment** (outdoor agriculture) – illustrating both the performance gains (sub-second local decisions) and engineering of robustness (network resilience, “graceful degradation”) highlighted in the ART.
- **“Siemens Reinvents Factory Reliability with Edge AI-Driven Predictive Maintenance” – Arm News (industry blog) – Aug 2025.** *Describes Siemens’ deployment of edge AI sensors in industrial automation.* According to this report, **Arm Cortex-based AI sensors** in Siemens production lines continuously analyze vibration, temperature, and power draw from motors and equipment on-site[22][23]. Upon detecting anomalies (e.g. a bearing overheating), the system can *instantly adjust machine parameters* (slow down or cooling) **in real time**, not just send an alert[24]. The benefits reported include reduced energy use and scrap rates and extended equipment life due to proactive interventions[25]. Notably, Siemens is also using generative AI models at the edge to anticipate component failures and self-calibrate the process with each cycle[26]. This commercial example shows a *well-capitalized actor deploying edge AI at scale* in mission-critical settings (factories), confirming high plausibility (the technology meets strict latency and safety requirements) and indicating a transition toward autonomous, self-optimizing industrial systems.
- **“2025 Edge AI Technology Report (Chapter: TinyML)” – CEVA Inc., industry tech report – 2025.** *Industry survey of edge AI use cases and deployments.* CEVA (a major edge AI IP vendor) highlights multiple **real-world applications shipped or in pilot**: e.g., an AI cough detector by Hyfe that runs on-device to diagnose respiratory illness while preserving privacy[27], an automotive system (Globalsense) that listens for crash events via smart audio sensors for instant emergency response[28], **voice-activated earbuds** from a top manufacturer achieving sub-20 ms on-device inference for user commands[29], and a motion-sensor-based fall detection solution in senior care that processes data locally to trigger rapid alerts[30]. These examples, spanning healthcare, automotive, consumer electronics and eldercare, underscore that **edge AI for sensor data is already entering products across sectors**. The diversity of players and domains, along with mention of platform tools (Edge Impulse, NVIDIA kits) enabling these solutions[31], is evidence of an active ecosystem moving beyond prototypes to practical deployment.
- **“TinyML chipset shipments forecast” – ABI Research (market data) – Q3 2025.** *Market analysis showing growth and dominant use-cases for TinyML (edge AI) hardware.* ABI projects TinyML chipset shipments to grow at **29% CAGR through 2030**, largely driven by **audio/sound processing and sensor-data analysis** use cases which together account for >80% of these shipments[32]. This indicates that industry demand for on-sensor AI is accelerating, especially for always-on audio (e.g. wake-word detectors, acoustic monitors) and IoT sensor analytics. The significant growth and investment forecasted implies that multiple vendors are scaling up production of edge-AI-enabled chips/devices. This serves as a quantitative indicator of maturity: edge AI is moving towards mainstream adoption with improving economies of scale, rather than remaining a niche laboratory concept.

- **“QUTE: Quantifying Uncertainty in TinyML models ...” – N. P. Ghanathe, S. J. E. Wilton – ICML 2025 (poster, peer-reviewed) – May 2025.** *Presents a method for on-device uncertainty awareness in TinyML models.* The authors introduce “QUTE,” an early-exit ensemble technique that runs on a **256 KB RAM microcontroller** to estimate the confidence of its own predictions[33]. In tests, QUTE’s approach reduced model size by 59% and latency by 31% compared to prior methods, while successfully detecting instances when the model’s accuracy would drop[9][10]. This is important for **reliability in edge AI** – the system can know when its sensor data is too ambiguous or degraded and possibly request help or fallback. The existence of such research and its feasibility on tiny devices confirms the ART’s claim that techniques for graceful degradation (uncertainty-aware detection, self-checks) are being actively developed to make edge AI robust in real-world conditions.
- **“Edge AI for atrial fibrillation detection on wearables” – E. Cinotti et al. – Sensors (MDPI, peer-reviewed) – Nov 2025.** *Demonstrates medical-grade AI inference on a wearable MCU.* This study embedded a 1D convolutional neural network on an ARM Cortex-M7 microcontroller (with an ECG analog front-end) to detect heart arrhythmia (AFib) from heartbeat intervals in real time[34][35]. The edge AI model achieved **96–98% accuracy** in detecting AF episodes on unseen subjects[36] – comparable to cloud-based analysis – while running within the MCU’s memory/power constraints. They built a complete battery-powered prototype that streams an ECG only when an arrhythmia is detected for physician verification[37]. This illustrates how *even safety-critical, high-accuracy applications* (health monitoring) are becoming feasible with edge AI. It also validates the value proposition of offloading processing from cloud to wearable: continuous monitoring with **minimal data transmission**, extended battery life, and instant alerts, aligning with the ART’s bottleneck-reduction claims for sensitive or bandwidth-heavy scenarios.
- **“Edge-Cloud Synergy for AI-Enhanced Sensor Network Data (Predictive Maintenance)” – K. Sathupadi et al. – Sensors/Electronics (MDPI, peer-reviewed) – Dec 2024.** *Reports a hybrid edge/cloud framework deployed for machinery monitoring.* The system uses **lightweight anomaly detection at the edge** (KNN model on sensor-node devices) and heavier LSTM models in the cloud for deeper trend analysis[38][39]. In a real-time experiment, this split approach achieved a **35% reduction in latency, 28% lower energy consumption, and 60% less bandwidth use** compared to a traditional cloud-only solution[40]. It shows that pushing initial AI processing to local sensor units yields significant performance and efficiency gains while still leveraging the cloud for periodic aggregation – a practical confirmation of the ART’s core rationale. The success of this system in a predictive maintenance context (monitoring industrial sensor streams) is evidence that edge AI can meet commercialization requirements: it improved response speed and cut costs, satisfying key metrics that would drive adoption in industry.

### 3. Maturity score (1–7) and reasoning

#### Proposed Maturity Score: 6 (Early mainstream adoption).

**A)** The balance of evidence suggests that *Edge AI for sensor data* has progressed beyond proofs-of-concept (Levels 3–4) into the **early product delivery and scaling phase (Level 6)**. Multiple well-funded companies and research groups have working prototypes **and** actual deployments: e.g. Bosch’s self-learning AI sensor and voice-activated earbuds (consumer products), Siemens’ AI-enabled sensors in factories (industrial systems), and several startups’ solutions in healthcare and agriculture[41][22]. These are not isolated lab demos but are being delivered to end-users or tested in real environments, indicating that the technology meets basic performance requirements for real-world use. Importantly, evidence

shows *recent and rapid progress* – many sources from 2024–2025 report breakthroughs like sub-second on-device vision[21], >95% accurate wearable AI diagnostics[36], and latency/energy advantages over cloud baselines[40]. Such achievements go beyond academic curiosity (Levels 1–2) and even beyond initial prototypes (Level 3), showing that **key bottlenecks (compute efficiency, model compression, etc.) have been solved well enough for fieldable solutions (Level 4)**. For instance, we see that constrained devices can now run useful neural networks within millisecond latency and millijoule energy budgets[8], and can even quantify their own uncertainty on-device[9] – milestones that eliminate what used to be blocking technical hurdles. There is also clear **commercial momentum**: industry reports and market forecasts confirm growing investment, with shipments of TinyML-powered chips projected to rise sharply and audio/sensor analytics driving that growth[32]. This implies several competitors are racing to capture markets (characteristic of Level 5+) and that early products are scaling up in volume (approaching Level 6).

**B)** We choose Level 6 because numerous *products are being delivered to customers*, albeit not yet with the ubiquity and market saturation of a fully mature technology. Evidence of delivery includes the Bosch BHI260AP smart sensor (integrated into wearables since ~2022), edge-AI-equipped devices in agriculture and healthcare that have been deployed in the field[21][41], and industrial edge AI installations by a giant like Siemens in live factories[22][24]. Customers are benefiting from these (e.g. reduced downtime, faster alerts), and early adopters span multiple sectors, fulfilling much of Level 6’s description (expanding application areas, internal financing of R&D by companies). **Lower maturity levels are clearly ruled out**: The technology is well past theoretical feasibility – core principles were proven and prototyped years ago (TinyML, in-sensor computing, etc.), and we now have *validated real-world performance data* (latency, accuracy, power usage) showing it can outperform cloud-centric approaches or classical sensor systems[40][21]. Even Level 5 (production prototypes and competitive development) has been exceeded in some domains: we have *shipping commercial products and multi-actor ecosystems* rather than a single prototype waiting for launch. For example, the ARM-Siemens collaboration and the Edge Impulse platform’s multi-sector use cases demonstrate at least a couple of major players actively deploying or supporting edge AI solutions, not just prototyping[22][30].

**C)** *What holds it back from Level 7?* In short, **edge AI for sensors, while promising, is not yet omnipresent or “plug-and-play” across all industries**. There are still notable challenges and constraints that the evidence and sources acknowledge, preventing full maturation: For instance, power/thermal limits force trade-offs in model complexity, meaning the most advanced AI capabilities (large models or very high accuracy under all conditions) still often require cloud support or new hardware innovations[42][43]. This is why hybrid frameworks (edge + cloud) are being developed – to compensate for edge devices’ limits[38][40]. Moreover, maintaining robustness “in the wild” remains a non-trivial task: techniques like QUTE are just emerging to ensure reliability under uncertainty[9][10], and extensive real-world validation is needed in safety-critical areas. The ART description itself flags that unit costs may initially be high and that extensive testing in extreme conditions (dust, low-light, etc.) is required. These factors suggest that **wider adoption and trust are still building**. In many organizations, edge AI is just entering pilot stages or niche deployments rather than being the default for all sensor systems. We do see competition forming, but a *fully mature Level 7 scenario* (with robust standards, broad customer demand and ubiquitous deployment) likely awaits further progress: for example, simpler development tools, more universal standards,

and proven long-term reliability. Recent surveys explicitly list open challenges like integration complexity and the need for unified Edge AI standards and benchmarks[12], indicating the field is still coalescing around best practices. In summary, the **score of 6** reflects a technology that has clearly demonstrated commercial value and is scaling up from early adopters toward the mainstream, but which needs a bit more time and refinement before it achieves the wide, competitive ubiquity and user confidence associated with Level 7. The strong evidence of working products and multi-player involvement rules out Levels 4–5, while the ongoing constraints and patchy deployment keep it just shy of the highest maturity level.

## ART 01.004 Quantum & High Precision Sensing

### Core Capabilities and Components

Quantum and high-precision sensing technologies exploit **engineered quantum states of matter and light** and **ultra-stable photonic or biochemical structures** to detect extremely small changes in physical quantities – far beyond the limits of conventional sensors. By harnessing phenomena like matter-wave interference and single quantum events, this family of sensors can make *“previously invisible phenomena measurable in routine settings.”* Key capabilities and components include:

- **Ultra-Sensitive Magnetometers:** Quantum magnetometers (e.g. using atomic vapor or diamond NV centers) can detect minute magnetic fields (femtotesla to picotesla scale) such as those from neural activity. These devices operate at room temperature and achieve sensitivities and dynamic range well beyond classical fluxgate or SQUID sensors. For example, researchers have demonstrated magnetometers capable of measuring tiny biomagnetic signals (brain waves) for medical diagnostics, a feat that previously required cryogenic equipment. Quantum magnetometers also offer high stability and do not require cooling, making them suitable for field use in geoscience and archaeology.
- **Optical Atomic Clocks:** Next-generation atomic clocks use optical-frequency transitions (e.g. in strontium or iodine-stabilized lasers) to keep time with **extreme stability**. These optical clocks “tick” at frequencies thousands of times higher than microwave clocks, making them tens of thousands of times more precise. Laboratory optical clocks can achieve such precision that they would lose less than a second over the age of the universe. Efforts are underway to miniaturize these clocks into **chip-scale or portable systems** without sacrificing too much performance. Such clocks provide ultra-stable time/frequency references for navigation, communications, and fundamental tests (e.g. enabling GPS-like positioning with centimeter accuracy in the future).
- **Quantum Gravimeters:** Using cold-atom interferometry, quantum gravimeters detect subtle changes in local gravitational acceleration. They can sense density variations underground (tunnels, voids, mineral deposits) by measuring the gravitational gradient with high resolution. In a 2022 field test, a portable cold-atom gravimeter was able to **map an underground tunnel** 1 m below the surface by detecting the tiny gravity dip it caused. The device discerned minute gravitational differences from

nearby structures that classical gravimeters would average out. Quantum gravimeters offer drift-free stability and high sensitivity, which can monitor geological or hydrological changes continuously without the long averaging needed by older sensors. Practical units remain somewhat bulky, but ongoing integration efforts aim for deployable systems for civil engineering, geophysics, and climate monitoring.

- **Cold-Atom Inertial Measurement Units (IMUs):** These devices use atom interferometers as ultra-stable accelerometers and gyroscopes. By splitting and recombining matter waves, they measure acceleration and rotation with unprecedented accuracy (potentially **orders of magnitude better** than today's best ring lasers or MEMS sensors). Quantum IMUs provide an **inertial navigation reference in GPS-denied environments**, with negligible drift over long durations. For instance, research prototypes with continuous cold-atom beams show high signal contrast and low noise, pointing to significantly extended navigation time without GPS aiding. While current devices are primarily laboratory prototypes, they promise to revolutionize submarine, spacecraft, or autonomous vehicle navigation once engineered into compact, rugged packages.
- **Single-Photon and Single-Molecule Sensors:** Advanced optical and biochemical sensors can register individual quanta – single photons of light or single molecules binding in a reaction. This capability allows detection of extremely low-concentration substances or weak light signals with **quantum-limited sensitivity**. In recent years, various biosensors have achieved *single-molecule* detection in different assay formats, enabling medical tests and environmental monitoring with unprecedented sensitivity. Likewise, single-photon avalanche diodes and superconducting nanowire detectors count individual photons for applications like LIDAR, quantum communication, and low-light imaging. These sensors often integrate into chip-scale photonic circuits or microfluidic devices, bringing quantum-level detection into portable, “routine” analytical tools.

**Integrated Design and Readout:** A unifying theme of this technology bundle is the push toward **miniaturized, integrable designs**. Many quantum sensors are being developed in chip-scale packages, optical fiber networks, or compact probe formats that can piggyback on existing instruments. They feature standard digital interfaces and on-board processing for calibration and noise filtering. Over time, these sensors “learn” background patterns and apply signal processing to isolate the quantities of interest. The goal is to deliver lab-grade sensitivity in field-deployable units – some as handheld tools or embedded modules, others as larger rack-mounted or cabinet instruments analogous to high-end lab equipment.

**Operational Constraints:** Despite their potential, these sensors face practical engineering challenges. They often require **strict environmental control** – magnetic shielding, vacuum chambers or low-temperature operation, vibration isolation, and ultrapure materials – to protect their fragile quantum states. Specialized lasers, vacuum hardware, or nanofabrication methods are needed to build and maintain them. Outside of controlled labs, maintaining calibration and performance is non-trivial; even minor vibrations or temperature fluctuations

can disrupt measurements. Robust packaging and self-monitoring systems are being designed to mitigate these issues (for example, robust quantum sensors that actively reject interference are under development). Regulatory certification for critical uses (like navigation or healthcare) will also be a hurdle until these devices prove long-term stability and reliability in real-world conditions.

**Value Proposition:** If successfully engineered, this family of sensors can alleviate key bottlenecks in current measurement and decision-making processes. They enable continuous, **non-invasive monitoring of slow or subtle processes** that today are impractical to observe. For example, quantum sensors could monitor structural health (by detecting minute strain or density changes) or agricultural soil conditions over large areas, without requiring destructive sampling or months of averaging. They can **reduce dependence on sparse reference infrastructure or expert operators** by allowing remote and automated measurements with lab accuracy. In domains where decisions are limited by coarse or infrequent data, quantum sensors offer more precise and timely insights – allowing tighter safety margins and early detection of issues. In summary, these technologies aim to provide **new eyes and ears** for industry and science, making the invisible visible and drastically improving the precision of our measurements in fields ranging from navigation and timing to medicine and materials analysis.

#### **Recent Key Developments and Sources (Last ~4 Years)**

To gauge the plausibility and maturity of this technology bundle, we collected a set of relevant, reliable sources from the past four years. These include peer-reviewed studies, industry roadmaps, government lab reports, and company technical disclosures, each highlighting progress in one or more of the component technologies:

1. **“Recent Progress of Atomic Magnetometers for Geomagnetic Applications” – T. Zhao et al. (Aerospace Info. Research Inst., CAS), *Sensors* (MDPI) review, 2023.** This open-access review details advances in optically-pumped atomic magnetometers and their use in geomagnetic surveys. It notes that modern alkali-vapor and helium atomic magnetometers have achieved nT to pT-level sensitivity at practical size/weight, making them **one of the most sensitive sensor types** for weak magnetic fields. The authors discuss engineering improvements (anti-vibration designs, micro-fabricated vapor cells) that now allow deployment in geophysics, archaeology, biophysics, and other areas. URL: <https://pmc.ncbi.nlm.nih.gov/articles/PMC10256078/>
2. **“First successful demonstration of a dual-media NV diamond laser system” – Fraunhofer IAF Press Release, Oct 2024.** Researchers at Fraunhofer IAF (Germany) reported a breakthrough in **laser-threshold magnetometry** using diamond NV centers. By integrating an NV-diamond crystal with a semiconductor laser diode in a single resonator, they achieved magnetic field detection in the femtotesla range with 100% signal contrast. The press release (summarizing a *Science Advances* article) highlights that **quantum diamond magnetometers are already widely used** for precise field measurements at room temperature, and this new dual-media laser

approach greatly extends sensitivity and dynamic range. The goal is to apply these sensors to measure tiny biomagnetic signals (e.g. neuron activity) for brain-computer interfaces and medical diagnostics. URL: <https://www.iaf.fraunhofer.de/en/media-library/press-releases/Demonstration-NV-diamond-laser-system.html>

3. **“Startups Squeeze Room-Size Optical Atomic Clocks Into a Briefcase” – D. Genkina, *IEEE Spectrum* (Feature article), Oct 15, 2024.** This article profiles the race to commercialize **portable optical atomic clocks**. It describes how three companies – Vector Atomic (US), Inflection (US), and QuantX Labs (Australia) – have each developed a compact optical clock that “*matches or beats*” existing commercial atomic clocks in stability, yet fits in a 3U rack or briefcase form factor. The piece explains the engineering trade-offs (reducing laser systems, using robust thermal vapor cell optics) that allowed Jun Ye’s lab-grade clock to be transformed into field-deployable products. These optical clocks are cited as **GPS backups** for timing in telecom, finance, and power grids, and as enablers of future navigation with cm-level precision. URL: <https://spectrum.ieee.org/optical-atomic-clocks>
4. **“Quantum sensor identifies underground tunnel” – H. M. Hill, *Physics Today News & Analysis*, Apr 1, 2022.** This news article reports on the first outdoor test of a **cold-atom quantum gravimeter** by University of Birmingham researchers. The quantum device (based on rubidium atom interferometry) successfully detected a 2-meter wide utility tunnel buried one meter below ground by measuring subtle variations in the local gravity gradient. Notably, the prototype achieved comparable or better accuracy than commercial classical gravimeters while requiring far less averaging time. The piece discusses how vibration noise was overcome by a unique dual-cloud interferometer technique, marking a significant step in making quantum gravity sensors practical for civil engineering (e.g. surveying infrastructure or archaeology). URL: <https://physicstoday.scitation.org/doi/10.1063/PT.6.1.20220401a/full/>
5. **“Quantum Gravimeter and Quantum Gravity Gradiometer Report” – ICV Tank (Tech Vision think-tank) analysis, Oct 30, 2024.** This industry report provides a **global overview of quantum gravity sensing** development. It outlines the evolution from lab concepts in the 2000s to the first commercial quantum gravimeters in the 2010s, and forecasts trends into the 2020s. The report finds that “*several companies have commercialized quantum gravity instruments,*” but notes that most quantum gravity **gradiometers** (which measure gradients for higher spatial resolution) are still at proof-of-concept or prototype stage, reflecting lower technical maturity overall. It highlights emerging players (startup and national lab spin-offs in Europe and China) and expects devices to become more compact and less expensive as the technology matures, potentially expanding use from military toward civilian applications like oil & gas exploration. URL: <https://www.icvtank.com/newsinfo/970240.html> (ICV Tank Quantum Reports)
6. **“Cold atom inertial sensors for navigation applications” – M.J. Wright *et al.* (Univ. of Liverpool), *Frontiers in Physics*, Oct 3, 2022.** This peer-reviewed paper examines the prospects of **quantum inertial sensors** in navigation. It reviews the fundamental

limits of inertial navigation and how atom-interferometer accelerometers and gyroscopes could mitigate drift in current systems. The authors note “*significant advances have been made to move these devices outside of the laboratory and into the real world*”, citing demonstrations of mobile cold-atom sensors. However, they also discuss practical limitations: current cold-atom IMUs have low update rates (Hz-level) and finite measurement dead-times due to the cooling cycle. The paper concludes that quantum IMUs will likely augment rather than fully replace classical sensors in the near term, for example by providing periodic ultra-precise calibration to a classical IMU to correct its drift. URL: <https://doi.org/10.3389/fphy.2022.994459>

7. **“China’s Space-Based Atom Interferometer Pushes Limits of Inertial Sensing” – M. Swayne, *The Quantum Insider*, May 16, 2025.** This article covers a major milestone: a **cold-atom quantum gyroscope in orbit** aboard China’s Tiangong space station. According to the report (summarizing a *National Science Review* publication), the Chinese team demonstrated rotation sensitivity on the order of  $50 \sim \mu\text{rad/sec}$  and acceleration sensitivity  $100,000\times$  better than a phone accelerometer. The device, roughly microwave-oven sized, uses rubidium atom matter-waves to detect tiny changes in motion, and achieved stable operation in microgravity. This achievement shows quantum inertial sensors working in one of the most challenging environments (space), underscoring their strategic potential to eventually supplement or replace conventional gyros in satellites, submarines, and spacecraft. URL: <https://thequantuminsider.com/2025/05/16/chinas-space-based-atom-interferometer-pushes-limits-of-inertial-sensing/>
8. **“Single-Molecule Optical Biosensing: Recent Advances and Future Challenges” – S. Dey et al., *ACS Physical Chemistry Au*, vol. 3, no. 2, Feb 2023.** This perspective (peer-reviewed) summarizes how optical biosensors have attained **single-molecule sensitivity** in various assay formats. It highlights improvements in photonic resonators, nanoparticle labels, and fluorescence techniques that now allow researchers to detect and count individual biomolecular binding events. The authors discuss the remaining challenges in moving these methods from lab to practice, such as integrating on-chip optics, handling complex real-world samples, and achieving continuous monitoring capabilities. Nonetheless, the article cites successful demonstrations of single-molecule detection in clinical diagnostics and environmental monitoring, illustrating the impressive biochemical sensing capabilities included in this technology bundle. URL: <https://pubs.acs.org/doi/10.1021/acspphyschemau.2c00061>
9. **“From fragile to field-ready: RoQS program launches first phase” – DARPA News Release, Aug 27, 2025.** This U.S. Defense Advanced Research Projects Agency announcement introduces the **Robust Quantum Sensors (RoQS)** program. It explicitly acknowledges that while quantum sensors offer unmatched precision, their “*extraordinary sensitivity has made them notoriously fragile in real-world environments*”. The RoQS program aims to redesign quantum magnetometers, gravimeters, and inertial sensors for field deployment by making them inherently robust against vibrations, acceleration, and electromagnetic interference. In Phase 1, teams will build

compact, “**walk-on/walk-off**” quantum sensors to be tested on a vibrating helicopter platform – a deliberately harsh environment. This reflects a systematic effort by a government agency to transition quantum sensing from lab to practical use, by solving engineering issues of hardening and manufacturability. URL:

<https://www.darpa.mil/news/2025/roqs-launches-first-phase>

10. “**NRL charters Navy’s Quantum Inertial Navigation path to reduce drift**” – U.S. Naval Research Lab Press Release, Apr 8, 2024. This release discusses a patent-pending **Continuous Cold-Atom Beam Interferometer** developed at NRL for next-generation navigation systems. The Navy’s researchers created a device that continuously feeds atoms into an interferometer, aiming to overcome limitations of pulsed cold-atom sensors. The press note explains that **quantum inertial navigation** could improve accuracy by orders of magnitude and reduce reliance on GPS. The NRL device achieved high measurement contrast and low noise by using a continuous 3D-cooled atomic beam, showing promise for maintaining long-term navigation with negligible drift. The Navy’s interest and ongoing R&D in this area underscores the strategic value of ultra-stable quantum IMUs for submarines and ships operating in GPS-denied scenarios. URL: <https://www.navy.mil/Press-Office/Press-Releases/display-pressreleases/Article/3734498/>

*(Additional sources: The above list highlights recent advances and efforts across the key subdomains of this technology bundle. Further references, such as national quantum technology roadmaps (e.g., Canada’s National Quantum Strategy on sensing) and standardization efforts, also corroborate the accelerating progress and investment in quantum and high-precision sensing.)*

#### **Overall Maturity Assessment (NETTI\_TUVJ 1–7 Framework)**

**Integrated Maturity Rating:** Based on the evidence gathered, the overall technology bundle “Quantum & High-Precision Sensing” is at approximately **Level 5** on the NETTI\_TUVJ maturity scale. This corresponds to the stage where a **proof-of-concept has been demonstrated and multiple well-funded actors are developing prototypes toward commercial products**. Some aspects are beginning to approach Level 6 (initial products delivered to early customers), but taken as a whole, the family of technologies has not yet achieved widespread deployment or fully proven robustness in everyday operational environments.

According to the NETTI\_TUVJ rubric:

- **Level 4 (Proof of Concept)** is surpassed: We have numerous functional prototypes that meet the basic performance requirements and clearly outperform prior solutions in sensitivity or stability. For instance, a quantum gravity sensor demonstrably detected underground structures better than classical instruments, and a chip-scale optical clock achieved short-term stability comparable to a hydrogen maser. These successes show that the core principles are proven in practical setups, not just theory or isolated lab experiments. Moreover, many prototypes have recently solved key material and engineering problems (e.g. portable gravimeters overcoming vibration

noise, or integrated photonic components stabilizing lasers for clocks), moving them beyond the lab-demo stage.

- **Level 5 (Competitive prototype development)** best describes the current state: There is now a “*competition situation with several well-capitalised market actors*” pursuing these technologies. Evidence of this includes multiple startups building optical clocks (Vector Atomic, Infleqtion, QuantX) all in parallel, at least two companies offering cold-atom gravimeters (e.g. Muquans/Exail in France and Q-Systems in the UK), and several vendors of quantum magnetometers (e.g. QZabre and SBQuantum for NV-diamond sensors, QuSpin for atomic vapor OPM sensors). Many of these firms have significant funding from VCs or government programs, and some are partnerships with large defense contractors (e.g. Safran’s work with DARPA on quantum inertials). The presence of **investment and prototypes in the “finishing phase”** is clear – for example, Infleqtion’s Ticker clock entered pilot production in 2024, and early units have been tested under field conditions (thermal, vibration) with minimal degradation. Progress is “*fast-paced*,” as new milestones are reported yearly (e.g. the first quantum gravimeter survey in 2022, the first space quantum gyro in 2025). This aligns with Level 5 criteria.
- **Level 6 (Initial products and scaling)** is on the horizon for some components but not fully realized across the board. Level 6 entails products being delivered to customers in increasing numbers and early scaling of production with cost reduction. We do see *partial signs* of this: for instance, chip-scale atomic clocks (CSACs, a prior generation of quantum clocks) are already commercially used in niche markets, and **Infleqtion’s Ticker Prime optical clock has multiple pre-production units built and tested** as of 2024. Similarly, quantum magnetometers based on optical pumping have been sold for applications like magnetoencephalography and mineral exploration (dozens of units, though not yet mass-market). Quantum gravity sensors have only a handful of deployments so far (mostly to research or defense customers), reflecting **low-volume, high-cost initial product status**. Even where products exist, they are often one-of-a-kind or small batch (e.g. a few optical clocks delivered to national labs or a defense agency). Economies of scale are therefore still unrealized – current devices remain expensive and require expert operation, which is why efforts like DARPA RoQS are focusing on ruggedization and manufacturability. In summary, **some elements are nearing Level 6**, but the *integrated bundle is best characterized as transitioning between Levels 5 and 6*.
- **Level 7 (Mature industry adoption)** – characterized by competing products widely delivered, rising demand, and self-sustaining growth – has **not** been reached. There is no broad market penetration yet for most of these sensors. Customer demand, while growing, remains mostly from specialized sectors (scientific labs, military, high-end industrial users) rather than a general market “pull.” For example, the ICV report notes that quantum gravimeters are still primarily used in military and research contexts, with civilian market expansion (like oil/gas exploration) still anticipated rather than realized. Similarly, the quantum timing and navigation devices are just beginning to

find pilot customers; we do not see “*customer demand on the rise*” in a mass-market sense – rather, it’s a targeted demand by niche stakeholders who are often directly involved in the R&D programs. Competition is present, but major industrial players are only cautiously entering (many efforts are still government-funded consortia or startups rather than, say, broad product lines from companies like Intel or Bosch, aside from a few exceptions). The criteria of Level 7 (significant internal financing by industry, wide adoption) are not broadly met yet.

**Justification with Evidence:** The assignment of **Level 5** is supported by concrete developments mapped to the rubric criteria:

- *Functional Proof-of-Concept Exceeding Prior Solutions:* Nearly every sub-technology has a working prototype that **demonstrably outperforms classical sensors** in core metrics. For instance, a quantum clock prototype by Vector Atomic achieves time stability better than high-end microwave clocks (losing  $\approx 1\text{s}$  in 32 million years), clearly exceeding previous standards. A cold-atom gravimeter in field tests showed 1.5–4 $\times$  lower uncertainty than a commercial gravimeter. These fulfill Level 4’s requirement of clear functional advantage. Additionally, the prototypes are not static – they show *recent significant progress*, such as the Fraunhofer dual-media magnetometer enhancing NV sensitivity into the fT range in 2024, solving a key problem to reach biomedical use.
- *Multiple Actors & Investment (Level 5):* There is robust evidence of a **competitive ecosystem** forming. The IEEE Spectrum report confirms “*in the past year, three separate companies have developed their own versions of compact optical atomic clocks*” – indicating a race among firms to commercialize the PoC. Likewise, the existence of *consortia and startup companies in quantum gravimetry* is documented, and DARPA’s RoQS program has drawn multiple performer teams to build field-ready sensors. This proliferation of players and funding corresponds exactly to Level 5’s hallmark: multiple well-capitalized entities pushing toward productization. The **fast pace of progress** is noted in sources like ICV Tank, which highlights *rapid development from 2020–2023* and increasing market confidence in quantum sensors.
- *Prototype to Product Transition (Levels 5–6):* We see that several prototypes are **entering the manufacturing and deployment phase**. Infleqtion’s Tiqker Prime optical clock is a prime example: it has a specific design for manufacture, with a 3U rack form, and a *pilot production line now underway* as of late 2024. Early units have been environmentally tested (thermal/vibration) and are being prepared for delivery to initial customers (likely government or large industrial labs). Similarly, QuSpin’s tabletop quantum magnetometers have been sold to research institutions for MEG brain imaging experiments, indicating initial adoption. These cases demonstrate partial fulfillment of Level 6 criteria – *products delivered in increasing (if still limited) amounts, with expansion financing in place*. Notably, venture capital and government grants have financed the scaling of these prototypes (e.g., ARPA-E funded Infleqtion’s clock development), suggesting that the **economic and manufacturing groundwork for Level 6 is being laid**. However, true economies of scale or broad market expansion are

not yet realized, as evidenced by the high costs and the fact that most devices remain custom-built or low-volume.

- *Constraints and Remaining Gaps:* The decision to not assign Level 6 fully (or Level 7) is justified by multiple source indications that **significant challenges remain before wide deployment**. The DARPA release explicitly states quantum sensors are “*notoriously fragile in real-world environments*” and are still largely lab-bound, requiring fundamental design changes to become field-viable. The Frontiers paper on inertial sensors explains that current devices have limitations (low update rate, dead times, limited dynamic range) that prevent them from replacing classical IMUs outright. These technical barriers translate to a slower commercialization timeline. Furthermore, the **market pull is still emerging** rather than present: as the ICV analysis notes, broader adoption in civil sectors is expected as devices become cheaper and smaller in the future – implying we are not there yet. Even the most advanced product, the optical clock, while debuting commercially, targets specialized uses like data centers and military timing where customers can tolerate high price and some complexity. This niche adoption, as opposed to ubiquity, is characteristic of Level 5/early Level 6 rather than a mature Level 7 technology.
- *Mixed Maturity Among Components:* It’s important to note that within this bundle, **different sub-technologies are at slightly different maturity levels**. For instance, single-photon detectors are arguably quite mature (SPAD sensors are in some consumer devices, which is a Level 7-like scenario for that narrow component), whereas quantum gyroscopes are still in one-off demonstrator stage (around Level 3–4 for a full IMU). According to the NETTI\_TUVJ framework, when an ART comprises several technologies at different stages, an average scoring is used if their applications differ. Here the applications do diverge (sensing magnetic fields vs. time vs. gravity, etc.), so an averaging approach is appropriate. The more mature elements (like certain optical/biochemical sensors already in products) raise the score, while less mature ones (quantum inertials) lower it – yielding an integrated assessment around the mid-range. We therefore assign **Level 5 as a balanced aggregate**. If one considered the subset of quantum timing and magnetometry alone, the score might lean closer to 6 given early products in use. Conversely, considering quantum inertial navigation alone might be Level 4 due to being mostly in research labs. **Level 5 captures the situation that fundamental feasibility is proven and the transition to practical products is actively in progress, but full deployment and routine use are still upcoming.**

In conclusion, **Quantum & High-Precision Sensing technologies are in the late prototype and early commercialization stage (Level 5)**. They have shown significant recent advancements and clear superiority over legacy sensors in performance, motivating strong investment and multi-actor development. Some first-generation products are reaching select end-users, hinting at Level 6, but the overall field must overcome further engineering and scaling challenges to achieve the robust, widespread adoption characteristic of Level 7. This Level 5 rating is supported by the documented achievements (proof-of-concept successes, multiple competing developers, pilot deployments) and tempered by the acknowledged limitations (fragility, cost, and nascent market uptake) evidenced in the sources above.

## ART 01.005 Micro/Nano Sensor Networks

### 13. ART extraction

**A) Primary capability:** Enable **massive, fine-grained monitoring** of physical environments and assets using swarms of *ultra-small, low-cost sensor nodes*. These “micro/nano” sensors would be **deployed in large constellations** to collect continuous data (e.g. temperature, vibration, chemical markers, humidity, light, etc.) with much higher spatial and temporal resolution than today’s instruments. They promise to **push sensing closer to the phenomenon** (even embedding sensors in materials or environments) and reduce reliance on sparse manual measurements, thereby catching early signs of faults or environmental changes.

### **B) Key sub-components/variants:**

14. **“Smart dust” sensor specks** – millimeter- or sub-mm scale wireless sensor nodes (often MEMS-based) with integrated sensors and micro-radios, sometimes called motes. Variants include *chip-based motes* (tiny CMOS/MEMS devices) and *chip-less tags* (e.g. purely passive resonant sensors).
15. **Flexible/thin-film sensor patches** – networks of *printed or flexible sensors* (e.g. on polymer films or stickers) that can be attached to surfaces or even worn. These often use *printed electronics* or *nanomaterial sensors* and can be made transparent or conformal<sup>[1][2]</sup>.
16. **Energy harvesting power sources** – ultra-low-power designs enabling nodes to run on *ambient energy* (light, heat, vibration, RF) or tiny batteries. This includes advanced

power management and, in some cases, *battery-free operation* via RF backscatter or piezoelectric harvesting[3][4].

17. **Low-power wireless communication** – specialized radios and protocols for tiny sensors, e.g. *backscatter communication* (reflecting ambient signals instead of transmitting[3]), Bluetooth Low Energy, UWB, or custom mesh networks. Must work under severe energy constraints and avoid spectrum interference.
18. **Edge processing & network architecture** – local microcontrollers or logic on the nodes for basic processing (thresholding, event detection) and multi-hop mesh networking to gateway nodes. Gateways handle heavier computation, data aggregation, and forwarding to the cloud. Over-the-air provisioning and firmware updates are included in the architecture.
19. **Scalable manufacturing & deployment** – methods to produce **billions of sensors** cheaply (e.g. leveraging CMOS/MEMS batch fabrication or roll-to-roll printing) and strategies to deploy them in the field (e.g. mixing with seed planters in agriculture[5][6] or integrating into equipment during manufacturing). Variants include *biodegradable sensors* for environmental deployment to avoid e-waste[6].

**C) Maturity indicators:** Evidence of this ART's progress would include: **laboratory prototypes** of millimeter-scale sensor nodes with full sensing/comm functionality; **field trials or pilot deployments** of large sensor networks (hundreds or more nodes) demonstrating continuous monitoring; **commercial products or platforms shipping** (e.g. sensor “dust” kits, battery-free sensor tags) and **multiple organizations investing** (startups, industry partnerships, government programs). Key indicators: working batteryless sensors with multi-month lifetime, reliable data relay at scale, compliance with regulations (radio emissions, safety), evidence of solving calibration and data management at scale, and early **adoption in real applications** (industrial condition monitoring, environmental sensing, etc.). Signs of competition (several well-funded companies or consortia) and **roadmaps for scaling to massive deployments** would also indicate increasing maturity.

## 20. Evidence (10–20 recent, reliable sources)

21. **Ultrathin Transparent Wireless Sensor Network (2024)** – Y. Jin et al., *npj Flexible Electronics*, Feb 2024. **(Peer-reviewed)** Demonstrates a **battery-free UHF RFID sensor tag** that is only 4.5  $\mu\text{m}$  thick and 90% transparent, for unobtrusive deployment on objects or skin[1][2]. Multiple such tags were wirelessly read over *room-scale distances (up to 8 m)*, tracking human motion and vitals without batteries[7][8]. *Why it matters:* Shows feasibility of **“invisible” sensor networks** embedded in environments, with *multiple nodes operating simultaneously* and communicating to a single reader. Achieves needed performance (meters-range RF comms, multiplexed sensing) in a tiny, flexible form factor – a strong proof that micro-scale sensors can be integrated and networked in real settings.
22. **Chip-less E-skin for Vital Monitoring (2022)** – Y. Kim et al., *Science* 377(6608):859, Aug 2022. **(Peer-reviewed)** Reports a **chip-less, wireless “electronic skin”** based on a *surface-acoustic-wave (SAW) sensor* on ultrathin GaN that monitors pulse, sweat ions, and UV exposure[9]. The device requires **no battery or IC chips**, instead harvesting and transducing mechanical strains into RF signals. Demonstrated continuous **week-long monitoring of a human pulse** with a purely passive patch[9]. *Why it matters:* Confirms the scientific feasibility of **dust-sized, battery-free sensors** with biomedical-grade sensitivity. It solved a key blocker (eliminating bulky chips/power) and maintained stable operation over days on a living subject[10], indicating that such microdevices can be made reliable enough for real-world use, at least in controlled scenarios.

23. **Smart Dust for Chemical Mapping (2025)** – I. Mondal & H. Haick, *Advanced Materials* 37:2419052, Mar 2025. **(Review – peer-reviewed)** A comprehensive review of *submillimeter-scale autonomous sensors* for environmental chemical sensing[11]. It notes that **several miniaturized sensor platforms have been demonstrated** – e.g. ingestible gas sensors for the gut and “aerosolizable” nano-electronic sensors that detect gases in air[12][13] – proving core sensing and communication principles. **However**, the review emphasizes that *smart dust development has lagged* other tech (like wearables) and faces ongoing challenges: limited multi-chemical detection, calibration complexity, device retrieval and environmental risks if billions are deployed[14][15]. *Why it matters*: It provides an authoritative reality-check – while the **conceptual and experimental groundwork is laid** for micro-sensor networks, issues of *scalability, reliability, and eco-safe mass deployment* remain. This indicates plausibility is high (no physical law barriers), but **maturity is still emerging**, requiring advances in multi-sensor integration, printable manufacturing, and data handling to reach practical deployments[16][17].
24. **Batteryless IoT Sensor Node Kit (2022)** – Everactive Dev Kit release, *EdgeIR*, Oct 2022. **(Industry news)** Everactive (US startup) launched a **batteryless IoT sensor system** powered by indoor light via a small solar cell[18][19]. Each wireless node measures temperature, humidity, pressure, and 3-axis vibration, transmitting data **every 15 seconds** using an ultra-low-power custom protocol, all on harvested energy[19]. The system includes cloud data visualization and is sold as a development kit (≈\$599)[20]. *Why it matters*: It proves a **commercial-grade prototype**: maintenance-free sensor nodes continuously streaming data in real time, without batteries. This addresses the key power constraint and shows that *data deluge and networking can be handled* (Everactive built a custom data delivery backend for the “massive influx” from these always-on nodes[21]). The availability of dev kits and initial customers means the technology is moving from lab to practical evaluation in industry.
25. **Industrial Partnership for Battery-Free Sensors (2023)** – Rockwell Automation press release, Sep 2023. **(Industry report)** Announces that Rockwell (major automation vendor) is partnering with Everactive to integrate **batteryless wireless sensors** into Rockwell’s industrial monitoring suite[22][23]. Everactive’s self-powered sensors (which harvest ambient energy) will feed into Rockwell’s FactoryTalk platform for continuous asset health data, *eliminating battery maintenance* in industrial sensor deployments[24][25]. Rockwell notes this will “*increase uptime... and customer profitability*,” and specifically highlights that **replacing batteries was a barrier** to wider use of wireless sensors[26]. *Why it matters*: This is evidence of **well-capitalized industry adoption**. A top-tier industrial player sees the technology as ready enough to invest and integrate – signaling that battery-free micro-sensor networks are *on the cusp of scaled deployment in real factories*. The partnership also suggests confidence in reliability (meeting commercialization requirements like ruggedness and data accuracy in harsh settings[27]).
26. **Mass-Scale Ambient IoT Tags (2026)** – Tageos & Wiliot joint announcement, *BusinessWire via AFP*, Jan 2026. **(Industry report)** Wiliot (IoT startup) and Tageos (RFID tag manufacturer) launched a new **battery-free Bluetooth sensor tag (“IoT Pixel” Gen3)** designed for **massive scale in retail/logistics**[28][29]. The passive tag harvests radio energy and broadcasts data on standard Bluetooth frequencies, transmitting item-level information like location, temperature, humidity, and motion to the cloud[29][30]. Tageos can produce the inlays at **up to 12 billion units/year** across facilities in France, US, China[31][32]. *Why it matters*: This shows the **infrastructure for scaling to billions of sensors is being put in place now**. Standardizing on Bluetooth Low Energy (global protocol) and leveraging existing supply-chain readers lowers deployment barriers. The enormous production capacity and a “Gen3” product imply that *multiple iterations and pilots have succeeded*. It underscores that micro-sensors as cheap,

disposable tags are moving toward *mainstream commercial rollout*, at least in supply chain applications (item tracking, cold-chain monitoring) where the value of dense data is clear.

27. **Air Quality Micro-Sensor Networks (2025)** – E. Bagkis et al., *npj Climate & Atmos. Sci.*, Oct 2025. **(Peer-reviewed review)** Surveys the deployment of **low-cost air quality sensor networks (LCSNs)**. Over the past decade, thousands of <\$2,500 sensors (many palm-sized or smaller) have been installed by citizens and cities, yielding **real-time, high-resolution pollution data** at local scales that complement sparse official stations[33][34]. However, it finds *significant maturity gaps*: lack of unified calibration methods or data standards, and difficulties in data sharing between different networks[35][36]. *Why it matters*: This is a **real-world use case of distributed sensors easing a measurement bottleneck** – more granular air quality monitoring – demonstrating the value creation of dense networks. It also highlights the **practical challenges of scaling up** sensor networks: even when individual sensors are cheap and widely deployed, ensuring data quality, consistency, and integration remains hard. The need for better calibration and protocols echoes the ART’s constraints (reliable manufacturing/calibration at volume, data handling). The LCSN experience thus supports the plausibility (people are indeed deploying lots of small sensors) but shows that **standardization and quality control** are key next steps for maturity.
  
28. **Energy-Harvesting Bluetooth SoC (2022)** – Atmosic Tech. press release, Jan 2022. **(Vendor technical doc)** Atmosic introduced the **ATM33 series Bluetooth 5.3 System-on-Chips** with integrated energy harvesting, aimed at IoT devices[37][38]. The chip achieves **extremely low power draw** (0.7 mA RF receive current) and can operate on ambient energy or vastly extend battery life (3–5× longer than competitors)[39]. It includes an ARM Cortex-M33 microcontroller and improved energy harvest circuits (broader input range, lower cold-start voltage) in packages as small as wafer-level chip-scale (for ultra-compact sensor designs)[38]. *Why it matters*: It shows **industry efforts to adapt mainstream wireless tech (BLE)** to micro-power domains. By cutting power consumption and adding energy harvesting, even standard protocols can be used in “perpetual” sensor nodes. This chip is essentially a *production-ready platform* for third parties to build tiny sensor devices that communicate with ordinary phones/hubs. The availability of such commercial components lowers the barrier to creating micro sensor networks and indicates that **multiple tech approaches (backscatter, custom mesh, and now BLE) are converging on feasible solutions** for ultra-low-power sensor communications.
  
29. **Biodegradable Soil Sensor Network Demo (2022)** – S. S. Pathak et al., *Scientific Reports* 12:9041, May 2022. **(Peer-reviewed)** Developed “**DIRTS**” – a **fully biodegradable, chipless wireless sensor tag** for subsoil monitoring[40][6]. The tags (made of biodegradable polymers and zinc foil) sense soil moisture via an RF resonance shift. They demonstrated deploying many tags *simultaneously with crop seeds* (distributed by a seeder) and reading them via a drone carrying an RF interrogator that scans the field[5][41]. Each tag operated reliably through a growing season, then **naturally decomposed** in the soil over months[6]. *Why it matters*: This is a **field-validated prototype of large-scale sensor deployment** – effectively a **wireless sensor network in an agricultural setting**. It tackles deployment and disposal challenges: sensors were deployed in bulk (one per seed) and required no retrieval thanks to biodegradability. The drone-based data collection also shows a novel solution to data backhaul for massive in-situ sensors. This experiment signals that even *cost-sensitive, hard-to-access scenarios can be addressed by micro sensor networks* when clever design (chipless passive sensing, eco-friendly materials) is employed. It boosts plausibility that the full vision (billions of tiny sensors in the wild) can be managed sustainably.
  
30. **Maturity score (1–7) and reasoning**  
**A) Final maturity score: 5 (Out of 7).**

**B) Justification:** The evidence places **Micro/Nano Sensor Networks at roughly Level 5** on the maturity rubric. We see that **key blockers at Levels 3–4 have been overcome in prototypes**: fundamental feasibility is proven by multiple lab demos (e.g. millimeter-scale, batteryless sensors measuring real phenomena[42][5]), and even **proof-of-concept deployments in realistic environments are underway**. For instance, Everactive’s battery-free nodes and Wiliot’s tags show that functional prototypes meet basic commercial requirements (continuous operation, integration with existing systems) – satisfying Level 4 criteria of a working PoC that is viable for production[25][19]. What pushes the score to *Level 5* is the **entry of well-capitalized and multiple actors**: at least two startups (Everactive, Wiliot, among others) have significant funding and industry partners, and large companies like Rockwell and tag manufacturers are investing to scale production[22][28]. This competitive and fast-moving development indicates the transition from isolated demos to **refining production prototypes and initial market launch**. Recent progress – e.g. partnerships and Gen3 products – has been rapid, matching the rubric’s description of Level 5.

**Evidence ruling out lower levels:** The ART is clearly beyond Level 2 or 3: it’s not just theoretical or a single lab device anymore. We have **multi-node networks functioning outside the lab** (the soil sensor field trial[5], ambient intelligence room with multiple tags[43]), and critical technical hurdles like ultra-low-power comms and energy harvesting have working solutions in peer-reviewed studies and commercial chips[3][39]. The existence of **real pilots and beta products** (batteryless sensor systems on sale, large-scale tag manufacturing) demonstrates that it’s no longer a tentative lab curiosity (Level 3) but a budding practical technology.

**Evidence lacking for Level 6:** To reach Level 6, we’d expect **broad customer deliveries and scaling production with economies of scale**. While there are early deployments, we do not yet see *wide adoption across industries or orders-of-magnitude shipment growth* publicly documented. The sources show pilot-stage and early adopter activity (e.g. “select group of customers” in 2021[44], or initial integration with Rockwell systems in 2023), but not that **competing products are widely delivered in increasing volumes** to many clients. We also see ongoing issues in standardization and data management (e.g. the air quality sensor networks still face calibration hurdles[35]), meaning the ecosystem is not fully mature. In short, **the foundation is laid and first products exist, but mainstream, scaled commercialization is just beginning** – which is characteristic of Level 5. Achieving Level 6 will require evidence of many thousands/millions of these micro-sensors deployed reliably, falling unit costs, and more autonomous large-scale data handling – developments not fully realized yet (but possibly within a few years given current trajectories).

**C) Sub-component breakdown:** This ART is a bundle of technologies, each at slightly different maturity, but all contributing to the overall vision:

- **Battery-free industrial sensors: Level 5–6.** Everactive’s self-powered sensor networks are **in pilot deployments with Fortune-500 partners**, and a major automation company is incorporating them[22][23]. This suggests near-production prototypes and initial scaling (on the cusp of Level 6, with financing and manufacturing in place, but not yet a ubiquitous product). Key source: Rockwell-Everactive partnership[22][25].
- **Passive ambient IoT tags: Level 5.** Wiliot’s Bluetooth IoT Pixel tags and similar are being scaled up with large manufacturing capacity[31] and have gone through multiple

generations. Big retail/logistics clients are testing them, but full deployment (billions in use) is just starting. Key source: Wiliot/Tageos 2026 press[29][31].

- *Micro-scale biomedical “dust”*: **Level 3–4**. Injectable or implantable micro-sensors (neural dust, etc.) remain in research and early trials. E.g. the SAW e-skin patch works in lab settings for a week[42], but no mass deployment yet. Motivation and funding exist (for medical diagnostics), so they are proven functional (Level 3) and approaching PoC (a body network of such devices would be Level 4). Key source: Science 2022 e-skin[9].
- *Printed/flexible sensor networks*: **Level 4**. We have prototypes like the transparent sticker network (room-scale demo)[43] and biodegradable soil sensors proven in field conditions[5][6]. These meet specific deployment needs (e.g. environmental monitoring) and show performance beyond classical approaches (no wires, minimal manual effort). They are essentially PoCs demonstrated in relevant environments, but not yet widely manufactured – consistent with Level 4. Key sources: Scientific Reports 2022 (soil)[5][6], npj Flex Elec 2024 (ambient stickers)[43].

These sub-components cluster around **Level 5 on average** – the more commercially pushed aspects (industrial and supply-chain sensors) pull the average up, while the more nascent areas (medical microdevices) pull slightly down. Since the ART’s **“functionality is largely the same across variants”** (all aim to densely instrument the world with tiny sensors), we assign the **overall score based on the leading edge** of progress. Level 5 is justified because **the core promise – cheap, pervasive sensor nets – is already in early commercial rollout in some domains**, even as other domains trail slightly. In summary, the strongest evidence of multi-actor investment and pilot-scale deployment (Level 5) outweighs the pockets of lower maturity, but the ART has *not yet fully proven* its ease of mass scalability and integration needed for Level 6.

## ART 01.006 Privacy Preserving Pervasive Sensing

### 31. ART extraction

32. **Primary capability:** Enables **continuous sensing with privacy by design**, ensuring that personal or sensitive data from ubiquitous sensors (cameras, microphones, wearables, etc.) is **processed and anonymized locally**. Only heavily **encrypted, aggregated, or de-identified information** leaves the device, preventing exposure of raw data.

### 33. Key sub-components/variants:

- *On-device analytics (Edge AI):* Sensors and IoT devices embed machine learning or signal processing locally to interpret data (e.g. speech recognition, image classification) without cloud upload.
- *Trusted hardware enclaves:* Devices use **secure chips/TEEs** (Trusted Execution Environments) to protect data and computations on-device, ensuring raw data and cryptographic keys remain isolated and tamper-resistant.
- *Privacy-preserving ML protocols:* Techniques like **federated learning** (devices send model updates instead of raw data) and **differential privacy** (adding noise

or aggregating results) allow collaborative analytics or model training while provably limiting personal data exposure.

- *Cryptographic data protection*: Strong encryption (in transit and at rest) and emerging methods (secure multi-party computation, homomorphic encryption) ensure that any data leaving the local environment is unintelligible without keys, or is only shared in statistical form.
- *Policy & interface layer*: Standardized software interfaces let users or admins **configure privacy policies** – deciding which sensors collect data, retention duration, and who (if anyone) receives processed outputs – enforcing privacy preferences and regulatory compliance by design.

34. **Maturity indicators**: Evidence would include **lab prototypes and field trials** of sensor systems achieving on-device processing with acceptable performance; **commercial product integrations** (e.g. smartphones, smart cameras) shipping with privacy-preserving sensing features; **standards or frameworks** (from consortia like IRTF/IEEE, or platform OS support like Android/Apple) that enable widespread adoption; **multiple industry players** investing in and competing on privacy-by-design IoT solutions; as well as **regulatory endorsements or compliance uses** (e.g. deployments seen as GDPR-compliant due to local data minimization). Signs of maturity range from research demos (e.g. privacy filters on microphones) up to **scaling deployments** (billions of devices doing on-device AI, federated analytics in real-world use). Key milestones include achieving real-time local analytics, power-efficient secure chips in low-cost devices, and organizations routinely choosing edge-resident data processing over cloud for privacy reasons.

35. **Evidence (10–20 recent, reliable sources)**

36. *Privacy-Preservation Techniques for IoT Devices: A Systematic Mapping Study* – D. Torre et al. – **IEEE Access (peer-reviewed)** – Jan 2023. [1][2] <br> *Survey of 260 papers (2017–2021) on IoT privacy techniques*. It finds **active research in cryptographic protocols, authentication, and privacy attack defenses** for IoT, underscoring that embedding privacy in IoT systems is a major R&D focus. This breadth of work (funded by DHS/AFRL) signals the scientific feasibility and interest in privacy-by-design IoT[1]. It establishes the landscape of tools (encryption, differential privacy, etc.) that underpin the ART’s plausibility.

37. *Privacy-Preserving Intelligence at the Edge: New Horizons in Federated Learning* – S. Mandava – **Preprint (SSRN)** – Mar 2025. [3][4] <br> *Evaluation of prominent federated learning (FL) frameworks in real edge environments*. Reports that FL can **train AI models across IoT devices without centralizing data**, improving performance and privacy by keeping data on the edge[3]. It notes fast development of FL for “privacy-preserving intelligence,” with enhancements in encryption and governance, and sees healthcare trials adopting fully privacy-compliant federated analytics[4][5]. This shows the core distributed learning approach of the ART is **operational in practice**, with frameworks benchmarking well on scalability and privacy-utility tradeoffs.

38. *“Protecting Audio Privacy at the Source” (Kirigami project)* – Y. Agarwal et al. (Carnegie Mellon University) – **ACM Ubicomp/MobiCom 2024 (peer-reviewed); news release** – Apr 2025. [6][7] <br> **Demonstrates on-device sensor filtering**: The *Kirigami* system runs on a tiny microcontroller and **automatically strips human speech from audio streams in real time**, before any data leaves a microphone[6]. It uses a lightweight classifier to delete speech segments while retaining other sounds for activity

recognition. This protects privacy even against advanced speech-recognition AI that could recover muffled speech. Notably, Kirigami is tunable (aggressiveness of filtering) and can be retrofitted to field-deployed mics[7][8]. This peer-reviewed prototype **solved a previously blocking problem** (open mics capturing private speech) and ran under the power/compute constraints of cheap IoT chips – strong evidence that privacy-preserving sensing is technically feasible for everyday devices.

39. *A Fallen Person Detector with a Privacy-Preserving Edge-AI Camera* – K. Hashemifard, F. Florez-Revuelta, G. Lacey – **ICT4AWE Conference (peer-reviewed)** – Apr 2023. [9][10] <br> **Prototype of a smart camera that never streams raw video.** Uses a Luxonis OAK-D edge-AI camera (with on-board Myriad X VPU) on a mobile robot to detect when an elder has fallen, as part of assisted-living tech. The team trained a YOLOv5 object-detection model (via knowledge distillation) to run entirely on-camera at **15 frames/s with 96.5% precision and 95.1% recall** for fall detection[10]. Only the **alert (fall detected)** is transmitted, not the video feed. This shows that fairly complex vision tasks can be executed locally with high accuracy and low latency, making continuous monitoring possible **without sending any identifiable video to the cloud**. It validates the ART's claim that edge processing can meet functional needs (fast, accurate detection) while drastically limiting data exposure.
40. *Privacy-preserving fall detection at the edge using Sony IMX636 event-based vision sensor and Intel Loihi 2* – L. Khacef et al. – **arXiv preprint (Intel Labs & partners)** – Nov 2025. [11][12] <br> **Cutting-edge “smart sensor” proof-of-concept combining a neuromorphic camera and processor.** An event-based vision sensor (Sony's IMX636, which outputs asynchronous pixel changes rather than images) is paired with Intel's Loihi 2 neuromorphic chip to detect falls with strict power and privacy constraints[11]. The system performs always-on inference at the sensor, consuming only ~90 mW on Loihi2. It achieved an **84% F1-score for fall detection** on a realistic dataset, using highly sparse spiking neural networks[12]. Notably, all computation occurs in a **secure, analog neural format on-device**, and only the detection result is output – the raw video is never produced in the first place. This exemplifies an emerging class of hardware designed for privacy-preserving sensing (in-sensor processing), showing that even **future-forward tech like neuromorphic AI is aligning with the ART's goals** to maximize privacy, latency, and energy advantages.
41. *Android Private Compute Core Architecture* – E. Marchiori et al. (Google) – **Technical whitepaper (arXiv) & Android open-source** – Sep 2022. [13][14] <br> **Industry deployment in OS:** Describes Android's *Private Compute Core (PCC)*, introduced in Android 12, as a secure OS partition for on-device data analytics. The PCC runs ML features like **Live Caption, Now Playing (music ID), and Smart Reply entirely on-device**, isolated from apps[13]. It also enables federated learning updates via “Private Compute Services” – devices receive model improvements and contribute encrypted gradients, but raw user data never leaves the device[15]. This open architecture (partly open-sourced) shows a major platform's commitment to privacy-by-design: hundreds of millions of Android phones now perform sensitive computations in a locked-down local environment, **sharing only model updates or anonymized stats**. This real-world adoption by Google demonstrates **commercial viability and scalability**, as well as compatibility with existing hardware (using secure enclaves and the phone's AI accelerators).

42. *Confidential Computing: Hardware-Based Trusted Execution for Applications and Data* – Confidential Computing Consortium (Linux Foundation) – **Industry consortium whitepaper (v2)** – Nov 2022. [16][17] <br> **Evidence of secure hardware adoption for IoT edge:** Reports that *confidential computing* techniques (hardware TEEs that keep data encrypted even during use) are “**already in use**” by software vendors and organizations, including deployment “at the network edge for IoT use cases”[16]. For example, devices can now store and process cryptographic keys and sensitive sensor data inside standard secure enclaves, achieving security formerly only possible with dedicated HSM modules[17]. This indicates that **specialized secure chips have become practical and are being scaled out** beyond the data center into edge/IoT devices. It validates the ART’s assumption that the cost and performance of secure processing hardware are now compatible with embedded sensing nodes.
43. *Privacy-preserving federated learning for collaborative medical data mining in multi-institutional settings* – R. Haripriya et al. – **Scientific Reports (Nature, peer-reviewed)** – Apr 2025. [18][19] <br> **Demonstration of cross-organization analytics without data sharing:** This study combined federated learning with transfer learning to train medical image classifiers (for chest X-ray TB detection, brain MRI tumor classification, etc.) across multiple hospitals **without pooling patient data centrally**[18]. Using adaptive aggregation methods, the federated models achieved accuracy on par with models trained on merged data, proving that high-precision AI diagnosis is possible under strict privacy constraints[20][19]. The work also introduced a novel FedAvg/FedSGD switching strategy to improve convergence. This is a **peer-reviewed validation in a sensitive domain (healthcare)** that privacy-preserving sensing and learning can deliver real-world utility. It also signals growing trust: medical institutions are beginning to adopt such techniques to comply with privacy laws while still extracting collective insights – aligning with the ART’s value proposition of easing data-sharing bottlenecks.
44. *Internet of Things (IoT) Edge Challenges and Functions (IRTF RFC 9556)* – J. Hong et al. – **IRTF Informational Report (research consensus)** – Apr 2024. [21][22] <br> **Standards-community perspective:** This report by the IETF/IRTF research group on IoT recognizes privacy as a **key driver for moving processing from cloud to edge**. It explicitly states that performing computations “closer to data generators” (IoT devices) and **aggregating/anonymizing data before sending to cloud is a major use-case** for edge computing in IoT[21]. The RFC notes that many IoT applications face privacy, latency, and cost requirements that “cannot be addressed by centralized cloud” and thus require distributed edge solutions[23][24]. The document provides a general model where edge nodes handle data management and analytics (Section 4.5.2) and even mentions techniques like homomorphic encryption for processing encrypted data[25]. This broad consensus by an international standards body underscores the plausibility of the ART approach and indicates that **the industry is coalescing around privacy-preserving edge architectures** as a path forward.
45. *Enhancing IoT privacy with artificial intelligence: Recent advances and future directions* – A. Tsouplaki et al. – **Internet of Things (Elsevier) – Review Article** – Nov 2025. [26] <br> *Contemporary survey of AI techniques for IoT privacy.* Highlights a taxonomy of approaches and identifies **federated learning and encryption as central methods** for protecting IoT data[26]. The authors review about 40 recent papers and note that combining AI with encryption, distributed learning, and anomaly detection can mitigate many privacy challenges. They emphasize “real and substantial results” achieved in major sectors via these techniques.

The survey's analysis of **implementation feasibility and gaps** shows that while further work is needed (e.g. on resource efficiency and ethical compliance), the core building blocks of privacy-preserving sensing (on-device AI, secure aggregation, etc.) have made tangible progress in recent years. This comprehensive assessment by academic and industry researchers reinforces that the ART's components are not speculative – they are active areas producing working solutions.

#### 46. Maturity score (1–7) and reasoning

**Score: 6 (Early commercial deployment).** The evidence suggests that privacy-preserving pervasive sensing is **well beyond laboratory proof-of-concept (Levels 2–3)** and even beyond isolated prototypes (Level 4). **Key elements are in active production use:** For example, billions of consumer devices now run on-device analytics in secure enclaves (Apple's devices, Android's Private Compute Core) and share only anonymized aggregates[13][14]. Multiple tech giants are **competing on privacy features** – e.g. Google and Apple tout on-device AI for voice, photos, etc., and startups and consortia are advancing enabling hardware and software – indicating a **Level 5+ commercial momentum**. We assign Level 6 because **products are being delivered at scale** and steadily improved: real customers are using these privacy-preserving sensor capabilities today (from smart cameras to health wearables), and adoption is growing as data regulations tighten. For instance, the CMU *Kirigami* filter (Level 3 demo in 2024) was quickly followed by smartphone OS integrations (Level 5–6 in the same timeframe), showing fast-paced progress[6][13].

*Justification:* Evidence of **shipping implementations** rules out Levels 1–4. Android's PCC and Apple's on-device AI deployments prove that the core “compute-at-edge with privacy” principle is *viable at scale* (Level 4) and has moved into widespread productization[13]. The presence of **multiple independent actors and consortia** (Google, Apple, CCC, healthcare collaborations, etc.) demonstrates we are at least at Level 5 – there is clear investment and competition to build out these features. We choose **Level 6** because the technology is **not just in prototype or pilot: it's in mass production and increasing use**. Secure IoT chip platforms and edge AI cameras are being rolled out commercially, and costs are expected to drop with scale (e.g. standard secure elements replacing costly bespoke hardware[16][17]).

However, we stop short of Level 7 because full **market penetration and “default” status** are not yet achieved. Many IoT deployments still rely on cloud processing, and not all sensor makers have adopted privacy-first designs. Some sub-components (like fully homomorphic encryption or standardized user policy frameworks) are still maturing and not ubiquitous. In other words, **the foundation is laid and substantial value is being delivered (Level 6), but the paradigm hasn't completely overtaken legacy approaches**. Continued advances in efficiency, industry standards, and regulatory pressure will likely drive it to Level 7 in the coming decade as privacy-preserving sensing becomes the expected norm.

*Sub-component breakdown:*

- **Edge AI analytics: Level 6** – Already in millions of devices (e.g. on-device fall detection cameras, offline voice assistants) and reducing need for cloud data[10].
- **Secure hardware (TEE/secure elements): Level 6** – Widely deployed in consumer and industrial devices; standardized solutions via ARM TrustZone, SGX, etc.[16].
- **Federated learning & encrypted analytics: Level 4–5** – Proven in pilots (Gboard, medical imaging) with ongoing improvements, but not yet standard in all products[18][19].
- **Privacy policy frameworks: Level 4** – Early standards (IRTF, ISO privacy-by-design) exist and some OS support for user data control, but full interoperability is nascent.

These aspects collectively support an overall **Level ~5.5**, which we round up to **6** given that the **most crucial components (local processing and secure data handling) are already at production scale**. The less-mature elements (e.g. broad federated learning adoption) currently limit the total realization of the vision, but they do not negate the fact that **the integrated approach is already delivering value in real products**. Thus, **6** best captures the ART's status: significant deployment and growth, on the cusp of becoming a standard practice once remaining pieces fall into place.

## ART 01.007 Quantum-Resilient and Secure Communication Networks

1. **ART extraction**
2. *Primary capability – quantum-resilient secure networks*: Enables end-to-end communications that remain confidential and authenticated even against adversaries with large-scale quantum computers. It prevents “harvest-now, decrypt-later” attacks by using cryptographic methods that cannot be broken by quantum algorithms, thereby future-proofing long-lived data and sensitive communications.
3. *Key sub-components/variants*: Post-quantum cryptographic algorithms (encryption and digital signatures) integrated into network protocols (VPN, TLS, 5G, etc.) to replace current RSA/ECC-based schemes; quantum key distribution (QKD) links optionally added to share encryption keys via quantum physics for extra security; upgraded network hardware (routers, base stations, SIM cards, etc.) and secure modules supporting these new algorithms; crypto-agility frameworks and policy engines that negotiate algorithm choices and key lengths dynamically for seamless migration as standards evolve; mechanisms for metadata protection and traffic-obfuscation to limit traffic analysis and impersonation (e.g. encrypting not just content but also headers/patterns); integrated monitoring and automated response systems to detect anomalies (key compromise, downgrade attacks, hardware tampering) and reroute traffic through trusted paths; and global interoperability standards and certification programs (e.g. NIST PQC standards, QKD protocol specs, telco guidelines) to ensure different organizations’ equipment can communicate securely and be audited for quantum-resistant security.
4. *Maturity indicators – evidence to look for*: Successful **field trials or pilot deployments** of quantum-safe communications over existing fiber, satellite, or wireless networks (demonstrating real-world feasibility); **lab prototypes in networking gear** (e.g. quantum-safe routers, 5G systems or QKD devices) achieving required performance and reliability; **multiple industry actors and consortia engaged** (vendors, telecom operators, cloud providers, national labs) competing or collaborating to develop standards and products, indicating significant investment; **standards milestones and adoption roadmaps** (e.g. NIST finalizing post-quantum crypto standards, telecom industry guidelines, government mandates with timelines for PQC migration); early **commercial offerings or hardware support** for quantum-resistant encryption (prototype services, software updates, or add-on cards available to customers); and evidence that **performance/cost constraints are being addressed** (e.g. acceptable latency and energy overhead in post-quantum encryption, successful integration of QKD with classical traffic, incremental upgrade costs comparable to normal tech refresh cycles rather than massive new infrastructure builds).
5. **Evidence (10–20 recent, reliable sources)**
6. **UK quantum-secure network demo – University of Cambridge (Optics/Photonics conference 2025)** – *Phys.org news (Cambridge press)* – Apr 2025. *Researchers from Cambridge and Bristol demonstrated the UK’s first long-distance ultra-secure*

quantum network (>410 km fiber between cities) using two types of QKD (keys encoded in single photons and entanglement distribution). They achieved the first quantum-secured video call and encrypted data transfer over this network[1][2]. This is the first time a large-scale network combined entanglement-based QKD with classical data links, showing that multiple quantum-safe technologies can operate together over existing fiber infrastructure – a significant feasibility milestone for quantum-resilient communications.

7. **Deutsche Telekom field trial of quantum entanglement over telecom fiber** – Deutsche Telekom T-Labs (press release) – Mar 2025. DT's innovation labs, with startup Qunnect, achieved 17 days of sustained entanglement distribution at 99% fidelity over 30 km of deployed fiber[3]. They also dynamically routed entangled photons across an 82 km fiber network in parallel with normal Internet traffic, maintaining >92% fidelity[4]. This long-duration field trial on real telecom infrastructure – the first by a major carrier – demonstrates that quantum link technology (for QKD or future quantum internet applications) can be stably integrated into today's networks without disrupting classical data, underscoring the practical plausibility of quantum-secure network layers.
8. **Nationwide quantum-safe network pilot in Singapore** – Telecoms.com (industry news) – Aug 2024. Singtel (Singapore's telecom) launched Southeast Asia's first National Quantum-Safe Network Plus (NQSN+) pilot, a platform employing modern quantum-resistant security to protect enterprise communications[5]. The initiative supports various network devices and is rolling out in phases – from lab integration testbeds to live trials – to validate interoperability and performance before full deployment[6]. Singtel's program (backed by govt. agencies) illustrates the transition from prototypes toward production: it provides a path for enterprises to trial quantum-safe links (using post-quantum encryption and QKD) and reflects growing telecom industry commitment to upgrading national infrastructure for the quantum era.
9. **Post-quantum encryption on 5G: SK Telecom & Thales trial** – Telecoms.com (industry news) – Dec 2023. Korean operator SK Telecom and security firm Thales tested quantum-resistant cryptography on a 5G standalone network, focusing on encrypting subscriber identity data to protect user privacy from future quantum decryption. The trial used Thales's post-quantum SIM cards in SKT's 5G core network[7]. While large quantum attacks aren't yet real, this shows telcos are proactively implementing PQC to counter "record now, decrypt later" threats[8]. SKT's demo indicates that mobile network infrastructure (5G) can be upgraded with post-quantum authentication/encryption without waiting for quantum computers to emerge – a key proof-of-concept for wireless network readiness.
10. **Hybrid quantum-safe network PoC in EU (Nokia & HellasQCI)** – Nokia & GRNET (press release) – Dec 2023. In Greece, Nokia and the national quantum consortium HellasQCI successfully completed a proof-of-concept Quantum-Safe Network over a three-node, optical fiber ring. The trial demonstrated a hybrid key management approach: using both classical cryptography and QKD-generated keys to encrypt optical data links[9]. Nokia's system included a security management server that orchestrated quantum-safe keys and continuously monitored the encrypted links, automatically reverting to classical keys if the QKD layer had issues[10]. This shows not only interoperability of QKD with standard network equipment but also the kind of policy-driven agility and fail-safe mechanisms envisioned (the network maintained

secure operation by switching algorithms on-the-fly). It's a concrete step toward commercializing quantum-safe transport networks in critical infrastructure.

11. **Cisco ships quantum-safe VPN encryption features** – Cisco Systems (vendor technical documentation) – 2023. Cisco has implemented post-quantum VPN capabilities in its IOS XE 17 routers, introducing support for the IETF's hybrid key exchange standard (RFC 8784). This feature allows mixing a Post-Quantum Key (PPK) into IKEv2/IPsec sessions[11]. Cisco's "Secure Key Integration Protocol" (SKIP) lets routers import keys from external quantum-safe sources (like QKD devices or a PQC key server) over a TLS channel, so that IPsec VPNs gain quantum-resistant pre-shared keys[12]. The feature is available on mainstream router models (Catalyst 8000, ASR 1000, etc.), indicating that quantum-resilient encryption is moving from lab to product: major networking gear now offers quantum-safe options that customers can configure for sensitive links.
12. **Global telecom industry coordination (GSMA Task Force)** – GSMA Post-Quantum Telco Network Initiative – Sept 2023. The GSMA (which represents mobile network operators worldwide) formed a "Post-Quantum Telco Network" task force in late 2022 to coordinate quantum-safe transition across the telecom sector. By 2023 the task force grew to 50+ companies (including ~20 major operators) and released quantum risk management guidelines for telcos at MWC 2023[13]. These industry guidelines help carriers assess quantum threats and plan upgrades (e.g. inventorying vulnerable systems, testing PQC algorithms in 5G/LTE, integrating QKD where applicable). The broad participation and formal guidance show that the telecom industry as a whole is actively preparing for quantum-resistant security, an important indicator of moving beyond isolated research to sector-wide readiness and standards.
13. **Government mandate for quantum-safe communications (USA)** – U.S. Federal initiatives (policy news) – May 2025. The U.S. government has issued directives to accelerate adoption of post-quantum cryptography in federal networks. A 2022 White House memorandum (NSM-10) requires federal agencies to transition to NIST-approved quantum-resistant encryption by 2035[14]. By mid-2024, agencies must update procurement requirements so new systems support PQC[15]. NIST finalized three core PQC standards (encryption and signature algorithms) in 2023[16], yet as of 2025 only ~5% of organizations have started deploying them[17]. Furthermore, the U.S. Office of Management and Budget estimates over \$7 billion investment will be needed this decade for PQC migration[18]. These mandates and resource commitments underscore that quantum-secure communication is technologically feasible and now a national security priority, though large-scale implementation is just beginning.
14. **Academic study – PQC standards and timelines (EU/US)** – Souvatzidaki & Limniotis, *Cryptography journal* – Nov 2025. A scholarly analysis of post-quantum TLS performance provides context on global transition plans. The European Commission issued a 2024 recommendation outlining a coordinated roadmap to shift EU organizations to post-quantum cryptography by 2035[14]. In the US, a national strategy likewise sets 2035 as the deadline for quantum-proofing federal systems (per NSM-10)[19]. The study notes that NIST's multi-year process has standardized five PQC algorithms (for encryption and signatures) by 2025[20], giving a clear basis for implementation. This evidence indicates the underlying science is settled and international standards bodies and governments have defined concrete milestones for

*rolling out quantum-resilient encryption in the coming decade – a strong sign of late-stage R&D transitioning into deployment.*

15. **Telecom Italia Sparkle quantum-safe service PoC** – Sparkle (TIM Group) press release – Aug 2024. Sparkle, a major global carrier, successfully ran a quantum-safe Network-as-a-Service PoC on its fiber network, and announced a commercial launch by year-end. The trial (in Athens) integrated post-quantum encryption from Arqit into an Intel-based network card and used Adtran’s software to automatically provision a secure “Quantum-Safe Internet” connection on demand[21]. It followed an earlier inter-country quantum-safe VPN test between Italy and Germany, and demonstrated fully automated setup of encrypted links using post-quantum keys within a standard NaaS platform[22]. Sparkle’s PoC showed that deploying quantum-resistant encryption can be as agile and cloud-managed as today’s services, and importantly that a commercial telecom sees the technology as viable for rollout (not just experiment)[23][24]. This reflects a competitive push to offer quantum-safe connectivity to customers, marking progress toward real-world productization.

#### 16. Maturity score (1–7) and reasoning

**Score: 5 (Proof-of-Concept demonstrated, moving toward commercial prototypes with industry momentum).**

**A) Rationale for score:** The evidence shows that quantum-resilient networking is **well beyond theory (levels 1–2)** and even beyond isolated lab demos. We have multiple successful **field prototypes and PoCs (level 3–4)**: e.g. sustained quantum entanglement in telecom fiber[3], long-distance quantum key distribution networks with live traffic[2], and post-quantum encryption trials in 5G and IP networks[25][11]. These achievements prove that the key technical hurdles (new algorithms, integration with existing infrastructure, basic performance feasibility) have been overcome in practice. Moreover, the transition is not limited to one team or one demo – **numerous well-funded actors are now involved (a hallmark of level 5)**. Telecom giants (Deutsche Telekom, BT, Singtel, Telefónica, etc.), networking vendors (Cisco, Nokia, Thales) and government programs (NIST, EU EuroQCI) are all running trials or developing standards in parallel[13][26]. This broad competition and investment indicate that the technology is in the **late prototype stage, approaching productization**. For instance, Cisco has already added quantum-safe VPN features to shipping routers[11], and Sparkle plans to commercially launch a quantum-safe service by the end of 2024[23][24] – these are strong signs of maturation beyond a proof-of-concept. Such momentum and multi-actor engagement rule out maturity levels 3–4, which correspond to single prototypes or early PoCs without industry uptake. We are effectively seeing the **first generation of market-ready solutions being prepared**, consistent with level 5.

**B) Missing evidence for higher levels:** The overall ecosystem has not yet reached full deployment or widespread customer adoption that would mark level 6 or 7. Level 6 requires products delivered at scale with rapidly increasing adoption. Here, most quantum-secure network implementations are **pilots or limited launches**, not yet rolled out across entire nations or to most customers. For example, Singtel’s and Sparkle’s quantum-safe networks are in trial phases[6][27], and while Cisco’s feature is available, only a small fraction of users have likely enabled post-quantum modes so far. We have no evidence of *broad* production deployment (e.g. thousands of quantum-safe links carrying everyday traffic) – adoption is cautious and just beginning (even U.S. agencies have only inventorying plans at this stage[17]). Additionally, **interoperability standards and certifications are still being finalized** (e.g. ITU/ETSI QKD specs, PQC in TLS/IPSec standards are emerging but not

uniformly implemented). The cost and complexity, while improved, are not yet “low friction” – specialized hardware (QKD devices, new chips) remains expensive and integration efforts are ongoing. These gaps mean the technology hasn’t achieved the market penetration or internal financing characteristic of level 6. In short, the concept is proven and attracting serious investment (level 5), but **full-scale commercialization and ubiquitous deployment are still on the horizon** (needed for level 6).

**C) Sub-component maturity breakdown:** This ART spans two main technology threads – **post-quantum cryptography (PQC)** and **quantum key distribution (QKD)** – plus supporting network control features. Each is at a slightly different stage, but they converge toward the same functionality (secure comms in a quantum era):

- *Post-Quantum Cryptography integration:* **Maturity ~5.** PQC algorithms have been standardized[20] and are being built into products: e.g. Cisco’s PQC VPN, Thales’s PQC SIM, and early adoption in protocols (TLS 1.3, IPsec)[11][25]. Multiple vendors and governments are driving this, with aggressive timelines (US and EU aiming for widespread adoption by 2035[14]). This suggests a transition from PoC to pre-commercial and pilot deployments, aligning with level 5 (active competition to implement and deploy).

- *Quantum Key Distribution and quantum networks:* **Maturity ~4.** QKD technology itself is proven (even deployed in niche uses), and recent field trials (UK, Germany, Singapore) show it can operate over metro/regional distances with high reliability[28][2]. Specialized firms (ID Quantique, Toshiba, etc.) do sell QKD systems, but these remain limited in scale and costlier than classical solutions. Integrated **quantum-secure network prototypes using QKD** (e.g. Nokia’s HellasQCI trial) are at proof-of-concept stage[9]; wider roll-out will depend on cost reduction and standardization. So QKD-enhanced networks lag slightly behind pure-PQC solutions in readiness – roughly at advanced field trial stage (level 4).

- *Network control, monitoring, and agility:* **Maturity ~4–5.** Software frameworks for crypto agility and threat monitoring are being tested: e.g. Nokia’s key orchestrator with automated failover from QKD to classical keys[10], and GSMA’s industry guidelines for quantum risk management[13]. These indicate concept validation (level 4) leaning toward level 5 as they get incorporated into pilot deployments.

Given that **the overall secure network solution can fulfill its core purpose with post-quantum cryptography alone** (QKD, while beneficial for certain high-security links, is an augmenting component), the maturity of the *bundle* is weighted more by the PQC integration track. PQC-backed network security is entering early commercialization, which justifies an aggregate score of **5**. In other words, the foundational capability – quantum-resilient encryption for network traffic – is approaching market readiness (level 5), even though some auxiliary elements (like widespread QKD or full metadata-hiding techniques) are still in prototype form. As those catch up, the ART as a whole will progress to the next level; for now, the evidence firmly places it at a mid-to-late developmental stage, **beyond proof-of-concept but not yet broadly deployed**.

## ART 01.008 Integrated Sensing and Communication (ISAC)

### 47. ART extraction

48. *Primary capability – “Integrated Sensing and Communication” (ISAC):* Simultaneous high-speed wireless data communication and radar-like sensing using the **same radio**

**network infrastructure.** The network's radio signals carry user data *and* probe the environment, allowing devices and base stations to act as distributed sensors while still providing connectivity.

49. *Key sub-components / variants:*

- **Joint waveforms & hardware reuse:** Unified radio waveforms and transceiver hardware that encode data and also measure signal reflections[1][2]. Co-designed **OFDM/communication signals for radar sensing** avoid separate sensors[1].
- **Network synchronization & MIMO arrays:** Tightly coordinated **multi-antenna** nodes (massive MIMO, distributed arrays) and precise timing enable coherent sensing across multiple transmitters/receivers[3][4]. Supports **monostatic, bistatic, multistatic** sensing modes and distributed aperture for higher resolution.
- **Sensor fusion & ML:** Advanced signal processing and **machine learning** fuse measurements from many nodes to infer object distance, velocity, and coarse shape, improving robustness over single sensors[5][6].
- **Standardization & spectrum sharing:** Integration into **5G/6G standards**, with spectrum management and regulatory frameworks for dual-use signals[7][8]. (E.g. studies in 3GPP Release-19 define ISAC requirements[9]; IEEE 802.11bf adds Wi-Fi sensing in license-exempt bands[10][11].)
- **Application variants:** *Short-range indoor:* e.g. Wi-Fi APs detecting motion in smart homes[12][13]. *Wide-area cellular:* 6G base stations acting as “**radar**” **networks** to track drones, vehicles, intruders, etc[14][15]. *High-frequency ISAC:* sub-THz links for ultra-high-resolution imaging and data together[16][17].

50. *Maturity indicators:* Evidence of **feasibility** (lab prototypes, field trials demonstrating comm & sensing concurrently), **standards progress** (3GPP study items, IEEE 802.11bf adoption[10][11]), **industry investment** (multiple major vendors and consortia launching ISAC programs[18]), and **early deployments** (proof-of-concept systems in real environments, or initial product features like Wi-Fi motion sensing). Key signs include **field trials** (e.g. 5G networks used as radar in airports[19]), **PoC demos** showing both data & sensing with one radio[1], **standardized features** in upcoming wireless releases[7][20], and even **commercial offerings** of integrated sensing capabilities (e.g. home routers with Wi-Fi-based motion detection[12][13]).

51. **Evidence (10–20 recent, reliable sources)**

52. **6G ISAC PoC on mmWave (Thorsten Wild et al., EuMW focus session)** – *Peer-reviewed conference paper (preprint)* – May 2023[1]. **Demonstrates a proof-of-concept ISAC system** using commercial 5G mmWave hardware with added sensing algorithms. It achieved **simultaneous high data-rate communication and OFDM radar sensing in the same band**, successfully detecting a pedestrian target. This result shows that future cellular networks can practically incorporate radar-like sensing without separate sensors[1]. (*Plausibility: Confirms feasibility on real 5G hardware; Maturity: early PoC resolving key integration challenges.*)
53. **Ericsson: “Sensing in 6G – Use cases and architecture” (R. Keller et al., Ericsson Tech. Review)** – *Industry technology article* – Oct 2025[7][21]. Reports that **3GPP is adding initial sensing features in 5G-Advanced** and envisions **fully integrated sensing in 6G**, enabling mobile networks to “actively sense” surroundings[7]. Describes Ericsson’s proposed end-to-end 6G architecture with sensing-capable base stations and core network functions. Identifies

use cases like **drone detection, collision avoidance for vehicles, and blockage tracking**, and notes significant market interest. (*Plausibility: Endorsed by a top vendor; Maturity: Standardization work underway now (Release 18/19)*[\[21\]](#).)

54. **Ropitault et al., “IEEE 802.11bf: Widespread Adoption of Wi-Fi Sensing” (NIST)** – *Peer-reviewed standards magazine* – May 2023[\[10\]](#)[\[11\]](#). Reviews the in-progress **IEEE 802.11bf amendment (target 2025)** that formalizes Wi-Fi sensing. The draft defines how ordinary Wi-Fi devices (2.4/5/6 GHz) can perform **bistatic and multistatic motion sensing** by sharing CSI (channel state) measurements. Example applications include presence detection and environment monitoring via Wi-Fi signals[\[10\]](#)[\[11\]](#). (*Plausibility: Validates that existing WLAN signals can double as sensors; Maturity: Task Group BF formed due to industry demand, standard nearing completion.*)
  
55. **ETSI Industry Specification Group on ISAC (press release)** – *Standards body announcement* – Nov 2023[\[22\]](#)[\[8\]](#). Announces **formation of a dedicated ISAC working group** with 87 participating organizations (incl. InterDigital, Apple, Huawei, etc.) to coordinate **pre-standard 6G ISAC research**[\[22\]](#). The group’s mission is to develop use cases, requirements, and evaluation methods, feeding into **3GPP Release 20+ and ITU-R IMT-2030** frameworks[\[8\]](#). Use cases span critical infrastructure security (intruder detection), smart cities, health (fall detection), and environmental monitoring[\[14\]](#). (*Maturity: Broad, multi-region industry engagement signals a concerted push toward 6G implementation.*)
  
56. **SESAR “NewSense” project (ENAC & partners)** – *EU research project report (completed)* – Oct 2022[\[19\]](#)[\[23\]](#). Developed and tested a **5G-signal-based radar surveillance system** for airport runways. The team added a 5G-based positioning function and used **reflected 5G base station signals to detect non-cooperative targets**, complementing a low-cost mmWave radar[\[24\]](#). Field trials at a Toulouse airfield showed the 5G-based sensing achieving **360° coverage with super-resolution and up to ~2 km range**, while the mmWave radar covered a few hundred meters ( $\pm 65^\circ$  FOV)[\[19\]](#)[\[23\]](#). This suggests a **cost-effective alternative** to expensive dedicated radars for smaller airports. (*Plausibility: Validated dual-use of 5G signals in a real environment; Maturity: Early field trial proving feasibility and economic advantage.*)
  
57. **Rohde & Schwarz – ISAC test solution & partnerships** – *Vendor technical doc / press* – 2023[\[25\]](#)[\[26\]](#). The test-equipment leader R&S developed a **laboratory platform for ISAC**, combining a commercial radar echo simulator with 5G/6G radio frontends[\[25\]](#). This setup generates **virtual targets** and measures a device’s simultaneous sensing/communication performance, enabling repeatable R&D testing. The solution earned a “*Most Innovative Mobile Tech*” award at MWC 2023[\[27\]](#). R&S also announced collaboration with **China Mobile Research Institute** to research and validate ISAC technologies[\[26\]](#). (*Maturity: Existence of specialized test gear and operator partnerships shows the tech is far enough along to require performance verification and attract telecom industry investment.*)
  
58. **6G Flagship (Univ. Oulu) D-band ISAC demo** – *Academic demo award (IEEE JC&S 2026)* – Jan 2026[\[16\]](#)[\[17\]](#). A research team in Finland built an **integrated 144 GHz (“D-band”) radio link** that delivered multi-Gbps communication *and* real-time **radio tomography imaging** simultaneously[\[16\]](#). Uniquely, the system used a single continuous link (fixed LoS) for sensing without any mechanical scanning, reconstructing 3D images of objects while transmitting data[\[28\]](#)[\[17\]](#). The demo ran remotely (controlled from Oulu) and was **noted for its technical maturity and robustness**, winning the Best Demo Paper award at IEEE JC&S 2026[\[29\]](#)[\[30\]](#). (*Plausibility: Demonstrates high-frequency ISAC working in practice; Maturity: A polished prototype achieving simultaneous comm+sensing in sub-THz, indicating rapid progress in the research community.*)

59. **Wang et al., “Terahertz ISAC with 220 GHz portable device” (Nature Comm.)** – *Peer-reviewed experimental paper* – Nov 2025[31][32]. Reports a **compact 220 GHz ISAC prototype** built with a phased-array transceiver using fully shared hardware for sensing and communication. The device can electronically scan  $\pm 30^\circ$  and was tested with a moving user terminal[31]. It achieves **millimeter-level imaging resolution** via an OFDM-based compressed sensing algorithm, *without* needing the slow raster-scanning typical of THz imagers[31][32]. This prototype delivered high-speed data links and high-resolution radar imaging concurrently, establishing a practical framework for unified THz comm+sensing devices. (*Plausibility: Confirms that very high-frequency (sub-THz) radios can be dual-purpose; Maturity: Key THz components and algorithms demonstrated, although still a research prototype.*)
60. **Comcast Xfinity “WiFi Motion” deployment (H. Nasir, Tom’s Hardware)** – *Tech news / product evidence* – Jul 2025[12][13]. Describes a **new feature in consumer Wi-Fi routers** that uses standard Wi-Fi signals for motion detection. Comcast enabled “WiFi Motion” on Xfinity routers, which analyzes perturbations in signal strength between the router and connected devices to **sense movement in the home**[12]. It can even detect small motions (like an arm wave) and distinguish a pet from a person, sending alerts via an app[33]. Crucially, this requires **no new sensors – only software updates** leveraging existing Wi-Fi radios. (*Maturity: Real-world product rollout – integrated comm-sensing has moved from lab to a value-added service for consumers, albeit with simpler sensing capability.*)
61. **3GPP Release 19 ISAC study (SA1 Stage 1)** – *Standards technical report (TR 22.837)* – Approved Sep 2023[9]. The 3GPP SA1 working group (services) completed a **feasibility study on Integrated Sensing and Communication** as part of Release 19. The study (100% concluded by 2023) defined initial **requirements and use cases for ISAC** in future 6G networks[9]. This Stage-1 work item, code-named FS\_Sensing, lays out how networks might incorporate sensing functions and what performance metrics and scenarios (e.g. accuracy, range, types of objects) must be supported. (*Maturity: Indicates that cellular standards development has formally begun addressing ISAC, a precursor to concrete specs in subsequent releases.*)

## 62. Maturity score (1–7) and reasoning

### Proposed Score: 4 (Proof of Concept demonstrated, clear path to commercialization)

**A) Justification for score 4:** The collected evidence shows that integrated sensing-communication has moved beyond theory and isolated lab demos into **system-level prototypes and initial trials**, but is not yet a mainstream deployed capability in cellular networks. Multiple prototypes (mmWave and THz) have **demonstrated key functionality** – e.g. using 5G/6G hardware to detect humans[1], or imaging objects via a live high-frequency link[34] – proving that the once-theoretical integration is technically **feasible (ruling out Levels 1–2)**. A number of **Proof-of-Concept systems** have been built and tested in relevant environments: for instance, the NewSense field trial showed a 5G-based radar functioning on an airfield with km-range coverage[19], and the Nature Comm. device achieved joint 220 GHz sensing/comm in a compact form[31]. These successes indicate that **previous blocking issues (waveform design, hardware sharing, etc.) have been solved in principle**, consistent with Level 3. Moreover, early **commercial forays** are underway – notably, **Wi-Fi sensing features are already shipping to customers** (Comcast’s router update in 2025)[12]. This suggests that at least in niche applications, integrated sensing meets real-world requirements and is being monetized, which is characteristic of Level 4 (PoC viability and

initial market introduction). The technology's appeal is also evidenced by **major industry participation**: dozens of companies and standards bodies (3GPP, IEEE, ETSI) are investing in ISAC R&D and roadmaps[18][9], implying strong commercial motivation and a race to refine the concept – a dynamic that begins to approach Level 5.

**B) Why not a higher score:** Despite rapid progress, **fully integrated sensing-communication networks are not yet delivering broad services to end-users**, which rules out Levels 6–7. There is **no multi-vendor commercial product (beyond Wi-Fi motion detection) that offers high-resolution ISAC** – current telecom deployments (5G) do *not* include radar-grade sensing, and 6G standards are still in exploratory phases[7][8]. Level 5 would require multiple well-capitalized vendors on the cusp of production prototypes; while competition is heating up (Ericsson, Nokia, Apple, Huawei all active[35]), their efforts remain in the research or pre-standard trial stage, not final product development. For example, the **flagship demos and trials are impressive but isolated** – a cohesive ISAC infrastructure (with privacy/security frameworks, cost optimization, regulatory clearance) has yet to be proven at scale. **Key evidence missing for Level 5** includes public demonstrations of near-commercial **prototypes in operational networks** or announcements of dedicated ISAC hardware lines ready for manufacture. In short, the **core promise (e.g. city-wide 6G sensing networks)** is still several years and one 6G cycle away from realization, keeping the maturity in the advanced PoC stage (4).

**C) Sub-component maturity breakdown:**

- **Wi-Fi (WLAN) sensing integration:** *Maturity*  $\approx$  6. Wi-Fi-based motion sensing is already **delivered to consumers** by dozens of service providers (Cognitive Systems' WiFi Motion technology) and recently by Comcast[12]. Routers and mesh systems can act as home occupancy sensors with just software updates[33]. This shows economies of scale (leveraging existing Wi-Fi chips) and growing client adoption, although the sensing functionality is relatively basic (motion, presence).

- **Cellular (5G/6G) network ISAC:** *Maturity*  $\approx$  3–4. Significant **experimental milestones** have been reached – e.g. a Nokia-led PoC detected pedestrians via 5G mmWave[1], and academic teams demonstrated integrated comms & imaging in sub-THz bands[34]. There's a clear path to **standardization (3GPP Rel-19+ studies complete)[9]** and vendors plan incremental feature rollout by 5G-Advanced/6G[20]. However, current prototypes are mostly in labs or testbeds; **no carrier-grade product** or large-scale pilot has fully validated cost, durability, and performance trade-offs in the field.

- **High-frequency (mmWave/sub-THz) ISAC devices:** *Maturity*  $\approx$  3. Research prototypes (often lab-bench setups) have shown **remarkable performance** – e.g. millimeter-accurate imaging at 220 GHz[31] – breaking technical barriers. Yet, these are early-stage demonstrators; practical challenges like output power, miniaturization, and robust mobile operation remain before commercial prototypes (Level 4) emerge.

**Overall:** The **bundled ART functionality is essentially the same – using one wireless system for two purposes – but spans different scales and timelines**. We therefore weigh the maturity by the **core envisioned impact**, which lies in cellular/wide-area networks. Even though Wi-Fi sensing is more mature, its scope is narrower. Taking an average, the evidence supports **Level 4**: integrated sensing & communication is proven in concept with initial viable implementations, and standardization plus industry momentum are actively pushing it

toward production in the coming years, but full commercialization (Level 5+) is not yet attained.

## Group 2 - Computing Hardware & Non-Von-Neumann Paradigms

### ART 02.009 Compute-in-Memory & Neuromorphic Chips

1. **ART extraction**
2. *Primary capability* – **Energy-efficient AI computing by merging memory and processing:** Compute-in-memory and neuromorphic chips perform computations directly where data is stored (e.g. in-memory matrix multiplies) or using neuron-like event-driven circuits, drastically reducing data movement and idle power. This promises much higher throughput-per-watt and lower latency for data-intensive tasks than conventional CPU/GPU architectures[1][2].
3. *Key components/variants* – **(a) Analog in-memory arrays:** Non-volatile memory devices (e.g. RRAM/memristors, phase-change, MRAM) in crossbar circuits that perform matrix operations in-place via Ohm's and Kirchhoff's laws[3][4]. **(b) Neuromorphic spiking cores:** Networks of transistor "neurons" that communicate via sparse, asynchronous spikes (events), implementing brain-inspired computing (e.g. Intel Loihi, IBM TrueNorth, BrainChip Akida)[5][6]. **(c) Digital near-memory integration:** Memory chips (HBM, DRAM, etc.) augmented with logic (PIM/PNM) to process data within or close to memory banks, improving bandwidth and efficiency[7][8]. **(d) Interface & software stack:** These specialized chips are being designed as accelerators (chips or chipllets) with standard I/O and programming frameworks (e.g. Intel Lava) to integrate alongside CPUs/GPUs[2][9].
4. *Maturity indicators* – **Prototype demonstrations solving AI tasks** (e.g. in-memory analog chips running neural nets with high accuracy[10] or spiking chips handling vision/speech in real-time[6]). **Energy/performance benchmarks beating conventional hardware** (e.g. TOPS/W, latency)[11][12]. **Multiple actors and funding:** major industry R&D (Intel, Samsung, IBM) and startups producing test chips or early products[13][6]. **Pilot deployments or products:** e.g. neuromorphic chips available in developer kits or used in concept devices[14][15]. **Progress on challenges** (device variability, noise, software tools): evidence of

improved analog precision, yields, and toolchains enabling scale-up[16][17]. Successful **integration in standard fabrication** (e.g. analog memory on CMOS at advanced nodes) and plans for commercialization.

5. **Evidence (10–20 recent, reliable sources)**
6. **NeuRRAM RRAM Compute-in-Memory Chip (Nature, 08/2022):** *Chen, Wong et al. – Peer-reviewed paper.* Demonstrated a **48-core analog compute-in-memory ASIC with 3 million RRAM devices monolithically integrated on 130 nm CMOS**, achieving on-chip inference for multiple neural nets with software-comparable accuracy. The NeuRRAM chip delivered **1.6×–2.3× lower energy-delay product and 7–13× higher compute density** than prior RRAM prototypes[18], showing that in-memory analog computing can significantly improve efficiency without sacrificing accuracy[19][20]. (*Plausibility:* Validates analog AI computation on real silicon. *Maturity:* It's a complete lab prototype running diverse AI models, a key PoC.)
7. **64×64 MRAM In-Memory Computing Array (Nature, 01/2022):** *Jung et al. (Samsung Advanced Institute of Tech.) – Peer-reviewed paper.* Researchers built a **28 nm 64×64 magnetoresistive RAM crossbar** with an innovative “resistance summation” analog MAC architecture to overcome low device resistances. The chip achieved **93.23% accuracy on MNIST digit classification** (vs 95.24% digital baseline) and **93.4% on face detection**[21][10] – matching software-level performance when scaled to deeper networks[10]. *Significance:* This was **the first demonstration of in-memory analog computing with commercial-ready MRAM**, showing viability of a *non-volatile memory already in volume production* for AI computing[22][23]. (*Plausibility:* Achieved high accuracy on real AI tasks. *Maturity:* Used foundry-friendly tech, indicating a path to product.)
8. **IBM “HERMES” Analog AI Chip (Nature Electronics, 08/2023):** *Abu Sebastian et al. (IBM Research) – Peer-reviewed paper (summary in EE Times).* Describes **IBM’s 64-core in-memory inference chip with ~4 million phase-change memory (PCM) synapses on-chip**, aimed at deep neural network acceleration[24]. The HERMES prototype reached **16.1–63.1 TOPS throughput at 2.5–9.8 TOPS/W**[11]. While its energy efficiency was slightly lower than some RRAM-based accelerators, it achieved the **highest throughput-density to date – >1.8× higher** than any prior resistive-memory AI chip[25], and **achieved best accuracy on CIFAR-10** among in-memory accelerators[26]. This shows that large-scale analog chips can operate at performance levels approaching today’s digital accelerators. (*Plausibility:* High throughput neural network inference demonstrated. *Maturity:* Big industry player validating analog AI; comparing against other designs signals a competitive race.)
9. **2,048-Cell MoS<sub>2</sub> Memtransistor Crossbar (Nat. Commun., 10/2025):** *S. Das et al. (Penn State) – Peer-reviewed paper.* Demonstrated a **wafer-scale in-memory compute array using two-dimensional MoS<sub>2</sub>-based three-terminal memory transistors (“memtransistors”)**. They achieved **>92% device yield** across 2048-cell arrays, extremely low write energy (~0.2 fJ per device), and 10<sup>5</sup> read endurance[27][28]. The memtransistor’s tunable analog conductance (via gate voltage) allowed on-the-fly confidence modulation to resolve ambiguous inputs, improving inferencing without retraining[29][17]. The array successfully classified MNIST digits in hardware. *Why it matters:* This addresses analog variability by introducing gate-control and shows **thousands of analog devices can be reliably integrated**, a step toward larger in-memory networks. (*Plausibility:* New device tech achieving high yield and function. *Maturity:* Still experimental materials, but points to overcoming scaling limits.)
10. **BrainChip Akida Neuromorphic Processor in EV (EE Times, 01/2022):** *S. Ward-Foxton – Industry news.* Mercedes-Benz tested BrainChip’s Akida spiking neural network chip in its **Vision EQXX electric concept car** for ultra-low-power keyword spotting[30][6]. The

neuromorphic approach was **5–10× more energy-efficient** than conventional voice recognition, helping maximize EV battery range[6]. Mercedes stated that although neuromorphic tech “is still in its infancy,” such systems “**will be available on the market in just a few years**” and could radically cut AI energy use when scaled throughout a vehicle[31]. *Notably*, BrainChip’s Akida chip was made available on Mini-PCIe boards for integration, moving beyond demos to a product for early customers[14][32]. (*Plausibility*: Confirms spiking chips can perform real in-cabin AI tasks. *Maturity*: An actual neuromorphic chip deployed in a prototype car and offered as a product, indicating initial market entry.)

11. **SynSense “Speck” Event-Driven Vision SoC (SynSense, 06/2023):** *SynSense Inc. – Vendor technical announcement.* SynSense (Zurich/China startup) launched **Speck™, the world’s first fully event-driven neuromorphic vision SoC** combining a 128×128 pixel dynamic vision sensor with a multi-core spiking CNN processor on one chip[33]. The SoC performs always-on vision tasks (gesture, face detection, etc.) in **<10 mW and <200 ms latency**[34]. It is fully configurable with capacity of 0.32 M neurons. **Over 100 industry and academic users** are already working with SynSense’s neuromorphic hardware and software, and in 2023 the company began offering a \$199 Speck development kit for wider adoption[15]. *Significance*: This marks a **commercially available neuromorphic sensor-processor product** for ultra-low-power vision, and an active user ecosystem. (*Plausibility*: Custom spiking chips can handle real-world vision. *Maturity*: Early market traction – developer kits and dozens of pilot users signal progress toward commercial use-cases.)
12. **Samsung Memory Processing Prototypes (Samsung/Semiconductor blog, 01/2023):** *Samsung Electronics – Industry tech disclosure.* Samsung showcased its **Processing-in-Memory (PIM) and Processing-near-Memory (PNM) technologies**. A High Bandwidth Memory PIM (HBM-PIM) prototype (integrating compute into HBM2 stacks) demonstrated nearly **2× performance and ~50% energy reduction** on AI workloads versus a GPU without PIM[35]. Samsung also unveiled **CXL-PNM memory modules** for servers and an “AXDIMM” (compute-in-DIMM) with on-board AI engines, which delivered ~2× performance in database inference and 40% system energy savings in customer tests[36][37]. *Why important*: Major memory vendors are pushing memory-compute convergence into real systems – in 2022 Samsung **integrated HBM-PIM into an FPGA accelerator, boosting system performance ~2.5× and cutting energy 60%**[12][38]. This indicates a path to **near-term commercialization in data centers and mobile devices**, albeit using more digital/near-memory approaches initially. (*Plausibility*: Confirms data-movement is a real bottleneck and memory-side processing works. *Maturity*: Prototypes tested with industry partners (Xilinx, SAP); standardization efforts underway – an early stage toward productization.)
13. **High-Precision Analog Computing SoC (Science, 02/2024):** *W. Song, J. J. Yang et al. (USC & Tetramem) – Peer-reviewed paper (reported by USC).* Researchers demonstrated a **memristor-based computing System-on-Chip achieving digital-level precision** on analog hardware[39][40]. By coding one high-precision value across multiple low-precision RRAM devices with a novel error-compensating weighting scheme, they achieved “**arbitrarily high**” **precision analog computation** (up to 16-bit+) while retaining orders-of-magnitude efficiency gains[41][42]. This solution was validated on a fabricated **memristor NPU chip (11-bit per device precision) built in a standard commercial fab**[43][16]. *Impact*: It overcomes the longstanding analog accuracy barrier, showing that analog in-memory accelerators can be scaled to higher precision and manufactured in modern foundries. The work, partially done at startup Tetramem, “**signals the potential for widespread commercialization of analog computing solutions**” combining high efficiency with accuracy[16]. (*Plausibility*: Solves analog precision and variability via architecture – a critical feasibility milestone. *Maturity*: The chips were made with industry partners and indicate readiness to transition from lab to fab.)

14. **Neuromorphic Computing Outlook (Nature Commun., 04/2025): D. R. Muir & S. Sheik – Perspective/roadmap.** A broad review of recent advances concludes that **neuromorphic and in-memory computing designs are on the cusp of commercial maturity**[2] after decades of R&D. Key enablers include *digital-friendly neuromorphic designs* (replacing earlier analog neuron circuits) and *gradient-trained deep spiking networks* that ease software development[44]. The authors note **multiple ongoing projects and prototype devices** (Intel Loihi 2, IBM’s memristive chips, BrainChip Akida, SpiNNaker2, SynSense Dynap, etc.) and highlight that **the remaining hurdles are being addressed** – e.g. standardized programming models and scaling to larger applications[45][5]. They predict ultra-low-power neuromorphic processors will soon find wide use in battery-powered gadgets, edge IoT, and wearables[46]. (*Significance:* Authoritative confirmation that the field has moved from theory to practical engineering. *Maturity:* Implies that a wave of **competitive product development** is underway and that solving software and deployment issues will “clear the way to commercial success”[46].)
15. **TSMC/ITRI 10 ns SOT-MRAM Array (ISSCC 2024 report): AllPCB Tech – Industry summary (09/2023).** Reports that TSMC and Taiwan’s ITRI demonstrated a **spin-orbit torque MRAM prototype** (an advanced memory for compute-in-memory) with **~10 ns operation speed** and significantly lower power than prior STT-MRAM devices[47]. This progress in emerging memory technology indicates that **faster, more energy-efficient non-volatile memories** will be available for tightly integrated computing. *Relevance:* High-speed, low-energy NVM like SOT-MRAM could overcome the latency and endurance limits in current in-memory accelerators, aiding commercialization (e.g. enabling on-chip memory computing at cache-like speeds). (*Plausibility:* Shows hardware improvements at the device level. *Maturity:* Involvement of a leading foundry (TSMC) and demonstration on 28 nm suggests these new memory devices are nearing readiness for product integration.)
16. **Maturity score (1–7) and reasoning**  
**Final Score: 5** (Prototype proven, entering competitive development phase)

**A) Why not lower:** The core principles have moved well beyond theory (levels 1–2) – multiple **physical prototypes now exist** (analog crossbar chips, spiking neuromorphic ASICs) demonstrating functionality that clearly exceeds conventional von Neumann efficiency[18][6]. Key previously-blocking problems (e.g. analog inaccuracy) have seen **concrete solutions in hardware**[41][42], and at least one neuromorphic chip is **commercially available in developer kits**[15] – evidence surpassing a mere lab demo (level 3). Several prototypes (e.g. IBM HERMES, Samsung MRAM CIM) are effectively **PoCs meeting performance goals** (energy per operation, accuracy close to digital baselines) that hint at viable products (approaching level 4)[10][25].

**B) Why not higher:** The technology is **not yet widely deployed in end-user products or large-volume production**. While early products exist (BrainChip Akida boards, SynSense Speck kits), these serve niche or evaluation markets rather than mass adoption – indicating we haven’t reached level 6’s “products delivered in increasing amounts.” The **ecosystem is still nascent**: software toolchains and programming standards are only now coalescing[44], and integration into mainstream computing platforms remains limited to pilot collaborations (e.g. Mercedes concept car, Samsung’s tests with Xilinx/SAP)[31][12]. To reach level 6, we would expect multiple competing products shipping and clear signs of scaling production, which are not fully evident yet (e.g., **no multiple vendors selling high-volume neuromorphic accelerators**—instead we see mainly prototypes and single-source chips). The **next missing evidence** for level 6 is a **significant uptick in real-world deployment** – for instance,

neuromorphic co-processors designed into consumer devices or edge servers in volume, and production lines ramping up with economies of scale. Also needed is a broader **market pull** (growing customer demand) – market forecasts are optimistic (tens of billions by 2029)[48], but actual orders are only starting. In short, progress is rapid and several well-funded players are in the race (characteristic of level 5), but sustained commercial delivery and competition (level 6) are just on the horizon.

**C) Sub-score assessment:** This ART spans **two converging threads** – analog *compute-in-memory* and *neuromorphic spiking processors*. The **compute-in-memory** side (memristor/PCM/MRAM accelerators) is around **level 4**: laboratory PoCs like NeuRRAM and HERMES have proven functionality and even solved key technical hurdles[18][25], but they remain prototypes; no mass-market product is out yet (production and software integration challenges remain). The **neuromorphic/spiking side** is closer to **level 5**: multiple startups and large companies are actively developing chips, at least one **commercial neuromorphic chip (Akida)** is shipping in small volumes[14], and big industry names (Intel, Samsung) are investing heavily – signaling competitive development and fast-paced progress. Since these sub-technologies ultimately target *similar applications (edge AI acceleration, low-power pattern recognition)* and are often viewed as complementary (or even combinable in one system), their maturity can be aggregated. Here we lean toward the higher end (5) because **the presence of early products and multi-actor competition** indicates momentum beyond isolated lab demos. In summary, **score 5** reflects that the science is proven and functional prototypes are transitioning to pilot deployments, with numerous actors racing to deliver the first broadly adopted products – the field is **poised on the threshold of commercialization**, but full-scale product uptake is still forthcoming.

## ART 02.010 Novel transistor technologies and materials beyond silicon CMOS

### 63. ART extraction

**A. Primary capability:** Enable digital computing components that far exceed silicon

CMOS limits in *energy efficiency, switching speed, and integration density*. These novel transistors operate at much lower power (even approaching reversible, near-zero dissipation), can be *stacked in 3D* or built into specialized subsystems (e.g. cryogenic logic), and maintain standard digital interfaces while unlocking new computing regimes (always-on ultra-low-power sensing, compute-in-memory, etc.).

#### **B. Key sub-components/variants:**

64. **Carbon nanotube FETs (CNFETs):** 1D carbon nanotube channels offering ballistic transport and  $\sim 10\times$  energy-efficiency gains over silicon, with potential for back-end-of-line (BEOL) integration[1][2].
65. **Two-dimensional (2D) material transistors:** Atomically-thin semiconductors (e.g.  $\text{MoS}_2$ ,  $\text{WSe}_2$ ) enabling extreme scaling (monolayer channels) and low off-current; can be grown or transferred onto wafers and even on flexible substrates.
66. **Spin-based logic devices: Magneto-electric** or spin-orbit devices (e.g. MESO) that use magnetization states for non-volatile logic at few 100 mV switching; promise attojoule-class operations via *voltage-controlled* magnetism[3][4].
67. **Tunnel/Single-electron transistors:** Steep-slope devices using quantum tunneling or Coulomb blockade to switch below the 60 mV/decade limit of CMOS; e.g. band-to-band tunnel FETs achieving sub-10 mV/dec slopes[5][6], or single-electron devices for ultra-low-power logic (often at cryo temps or via special structures).
68. **Reversible and superconducting logic:** Adiabatic superconducting circuits (e.g. AQFP, RSFQ) that can *recycle bit energy* and approach Landauer's limit of  $kT \ln 2$  dissipation[7][8]. Superconducting Josephson junction devices (operating at  $\sim 4$  K) switch picosecond pulses with  $\sim 10^4$ – $10^5\times$  lower energy than CMOS, enabling high-speed logic with minimal heat (at the cost of cryogenics).

**C. Maturity indicators (evidence sought):** Demonstrations of working **prototype devices and circuits** beyond theory – e.g. **lab prototypes** of transistors or logic gates with record performance (steep subthreshold swing, THz speeds, non-volatility, etc.), **integrated circuits** (ring oscillators, processors, memory arrays) built with these technologies, **wafer-scale fabrication yields** and uniformity reports, **scaling to larger arrays or 3D stacks**, involvement of **major industry consortia or roadmaps** (showing commitment to commercialization), and any **proof-of-concept system** (such as a specialized co-processor or sensor node using these transistors). Evidence of **compatibility with existing design flows or fabs** (e.g. 300 mm wafer processes, monolithic 3D integration in foundries) and of addressing reliability, variability, or cost challenges would also indicate progress toward viability.

69. **Evidence (10–20 recent, reliable sources)**
70. **Wafer-scale carbon-nanotube transistor arrays (2025)** – Yang Liu et al., *Nature Communications*, 12/2025. **(Peer-reviewed)** Demonstrates **4-inch wafer** fabrication of CNFETs with  $>98\%$  yield and high uniformity. Using solution-sorted semiconducting CNTs, they built memory-like charge-trap transistors and showed consistent performance across 300 devices (variation  $<6\%$ ). This indicates that CNT devices can be made at wafer scale with CMOS-compatible methods[9][10] – a key step toward large-scale integration. (Plausibility: high; Maturity: prototype wafer-level process)
71. **Monolithic 3D integration of CNT circuits in a foundry (2024)** – Andrew C. Yu (MIT), *PhD Thesis*, 2024. **(Technical report)** Established a **back-end-of-line (BEOL) carbon nanotube CMOS** process *inside a commercial 300 mm foundry*. Developed techniques for transferring and fabricating CNT-FETs atop silicon layers, achieving **monolithic 3D integration** of CNT logic on CMOS with improved reliability[11][12]. This shows that CNT transistors can be integrated

with existing silicon flows, paving the way for stackable logic-memory chips. (Plausibility: high; Maturity: lab/demo integration in fab)

72. **High-mobility 2D MoS<sub>2</sub> films and 2D ICs (2025)** – Ning Xi et al., *Nature Comm.*, 2025. **(Peer-reviewed)** Reported a **room-temperature processed MoS<sub>2</sub> monolayer film** (no high-temp steps) with carrier mobility up to 68 cm<sup>2</sup>/V·s, exceeding CVD-grown film mobility[13]. Achieved uniform TFT performance across an 8-inch wafer and built logic circuits: inverters, OLED drivers, and ring oscillators. The **5-stage ring oscillator reached >300 kHz** – the fastest for solution-processed 2D electronics (previous ~1 kHz)[14]. This evidences both performance and scalability improvements in 2D-material transistors. (Plausibility: high; Maturity: lab IC prototypes on wafer)
  
73. **Medium-scale flexible MoS<sub>2</sub> circuits (2024)** – Y. Peng et al., *Nature Communications*, 12/2024. **(Peer-reviewed)** Demonstrates **flexible integrated circuits** using monolayer MoS<sub>2</sub> TFTs. By improving fabrication, they achieved >90% device yield and built logic modules (NAND, XOR, latches) and a 112-transistor **clock divider** on plastic[15][16]. The circuits operate with full rail-to-rail logic swings. This exemplifies a complex IC (hundreds of devices) on 2D semiconductors, highlighting progress in device uniformity and circuit functionality at ambient conditions. (Plausibility: high; Maturity: prototype IC for niche (flexible) apps)
  
74. **300 mm wafer integration of 2D FETs (2023)** – C. J. Lockhart et al. (imec/Intel), *IEEE IEDM 2023 & imec report*, 12/2023. **(Industry roadmap/report)** imec and Intel **fabricated WSe<sub>2</sub> p-FETs on a 300 mm silicon wafer**, using a flow similar to MoS<sub>2</sub> n-FETs[17]. They analyzed grain size effects and reliability on these wafer-scale 2D transistors. This first 300 mm demonstration shows that 2D materials can be processed in an industrial fab environment, a crucial milestone for eventual high-volume manufacturing[17][18]. (Plausibility: high; Maturity: early fab-level demo, no product yet)
  
75. **Direct 2D material growth on chips (2023)** – MIT News (A. Zewe), 4/2023. **(University news, covers peer-reviewed work)** Developed a low-temperature CVD process to “**grow**” **monolayer MoS<sub>2</sub> on fully fabricated 8-inch CMOS wafers** without damaging them[19][20]. The method yields uniform 2D films in <1 hour (vs >1 day traditionally) and avoids manual transfer. This suggests 2D semiconductors can be directly integrated atop silicon circuits for high-density 3D chips[20][21]. It underscores engineering progress toward commercial integration of 2D transistors for denser, heterogeneous chips. (Plausibility: high; Maturity: process innovation at pilot scale)
  
76. **Sub-thermionic 2D/silicon tunnel FET (2022)** – J. Miao et al., *Nature Electronics*, 10/2022. **(Peer-reviewed)** Demonstrated a **heterojunction tunnel transistor** using a 2D InSe semiconducting layer on silicon, achieving **ultra-steep switching**: a 6.4 mV/decade subthreshold slope (average 34 mV/dec over 4 decades) and I<sub>ON</sub>/OFF ≈ 10<sup>6</sup>[22][5]. On-state current was 0.3 μA/μm @ V<sub>D</sub> = -1 V – low, but a clear proof that band-to-band tunneling in 2D materials can overcome the CMOS 60 mV/dec limit at room temperature. This validates the scientific feasibility of ultra-low-voltage logic devices. (Plausibility: high; Maturity: device concept proven in lab, needs higher drive current)
  
77. **Voltage-controlled spin logic (MESO) device (2024)** – M. Salamanca-Riba et al., *Nature Communications*, 2024. **(Peer-reviewed)** Researchers built a **magneto-electric spin-orbit (MESO) nanodevice**, the first experimental MESO implementation. A BiFeO<sub>3</sub> multiferroic was used to switch a coupled ferromagnet with <5 V pulses, and a Pt/CoFe spin-Hall structure read out the magnetization electrically[3][23]. They showed reversible 180° magnetization switching by purely electrical means and distinct output voltages for the two magnetic states. This confirms the MESO principle (voltage-driven, non-volatile logic at potentially ~attojoule

energies) in a prototype device[3][24]. (Plausibility: medium; Maturity: fundamental device demo, one bit)

78. **48,000-Josephson-junction superconducting circuit (2022)** – J. Strong et al., *Nature Electronics*, 3/2022 & *TechXplore*, 4/2022. **(Peer-reviewed & news)** Northrop Grumman built a **Reciprocal Quantum Logic (RQL) test chip** with 48k Josephson junctions operating at 3.5 GHz[25][26]. They implemented a novel metamaterial clock distribution network to deliver uniform AC power across a 3×3 mm<sup>2</sup> chip (<1 dB variation) at ~30% energy efficiency[27][28]. This demonstrates that **large-scale superconducting logic VLSI** is technically feasible, addressing a key bottleneck (clock/power delivery) for scaling up to millions of junctions. (Plausibility: high; Maturity: proof-of-concept computing fabric, still experimental and cryogenic)
79. **Reversible cryogenic logic near Landauer limit (2025)** – Q. Herr (imec), *arXiv preprint*, 4/2025. **(Preprint – simulation study)** Analyzes **adiabatic quantum-flux-parametron (AQFP)** superconducting logic with realistic variations. Shows that by copying inputs and using a “terminate” gate, logic operations can dissipate only ~7× the Landauer limit (kT ln2 per bit) even with 1% device parameter spread[7][29]. Idealized circuits can approach true reversible computing with energy dissipation proportional to information lost[30][31]. This suggests *in principle*, superconducting adiabatic circuits could perform complex logic with negligible heat – highlighting a path to ultra-efficient (level 1) computation if manufacturing challenges are solved. (Plausibility: medium; Maturity: theoretical validation, experimental verification pending)

#### 80. Maturity score (1–7) and reasoning

##### A. Final score: 3 (Laboratory prototype demonstrated).

**B. Justification:** The evidence shows that fundamental feasibility has been **proven in the lab** for all major variants – many have working prototypes solving previously blocking issues, but none are yet at a proof-of-concept *product* level. Level 3 corresponds to “a laboratory prototype demonstrated... key problems solved, functionality achieved, but production and durability issues remain.” This fits well:

- **Level 2 ruled out:** We have gone beyond mere principle demonstrations – e.g. CNT transistors are not only theory or one-off devices; a **16-bit microprocessor with 14k CNFETs** was built (2019) and recently **wafer-scale CNT device arrays with 98% yield** were shown[9]. Similarly, sub-thermal **TFETs** and **MESO spin devices** are experimentally realized[5][3]. These successes indicate progress past the initial “model verified in lab” stage; we are now engineering functional circuits, marking at least Level 3.
- **Why not Level 4?** Level 4 (proof-of-concept meeting *commercial* viability metrics) isn’t reached because none of these technologies yet meet **all the practical requirements** for commercialization in real products. For instance, **CNT chips** still face scaling and uniformity limits (the 16-bit CNFET CPU operated at kilohertz speeds on older nodes[2], and while manufacturing issues like metallic CNT removal are greatly improved[32][33], CNT CMOS is not yet beating silicon CMOS performance). **2D FETs** have been made on 300 mm wafers[17] and even stacked on CMOS[20], but device variability, contact resistance, and low drive currents persist[18]. No 2D or CNT logic has shown clear *cost or performance superiority* over incumbent tech in an actual application – a criterion for Level 4. **Spin logic (MESO)** is at a very early device stage (one-bit cells in lab) and **superconducting circuits** – despite large prototypes – remain impractical beyond niche uses due to cryogenic overhead (no commercial computer built from 50k JJ RQL yet). Essentially, each sub-tech is *motivated* by clear benefits

(e.g. steep slopes, non-volatility, no Joule heating), but **collectively** they are still solving integration and reliability challenges rather than approaching product rollout. There are not yet “production prototypes” or multiple companies racing to commercialize general-purpose CNT or 2D logic – development is mostly in consortia and research labs (industry roadmaps target ~2030+ for deployment[34]). Thus Level 4 – which requires a demonstrated viable product prototype or clear commercial path – is premature.

**C. Sub-score assessment by variant:** *(We consider the bundle’s application as extending digital logic – so we will average the maturity, as different approaches address similar needs in different ways.)*

- **Carbon nanotube FETs:** *Maturity ~3.* Demonstrated in complex circuits (a microprocessor, analog sensor interfaces)[2], and recently integrated in 3D with CMOS[11]. Key material issues (purity, alignment) largely solved, but needs higher speed and industry adoption.
- **2D material transistors:** *Maturity ~3.* Shown to work in medium-scale circuits[15] and scaled to 300 mm wafers[17]. However, performance (drive current) and device variability need improvement; no commercial 2D logic products yet.
- **Spin-based (MESO) logic:** *Maturity ~2.* Only basic devices and small gates in lab[3]; significant work remains to integrate these at scale or room temperature. Backed by Intel research, but no prototype circuits beyond few devices.
- **Tunnel/steep-slope devices:** *Maturity ~2–3.* Steep TFETs have been made with record swings[5], but on-currents are low and no large-scale integration yet (some TFET CMOS demonstrators exist, but not outperforming MOSFETs in practice). Single-electron transistors are mostly at physics experiment stage.
- **Superconducting & reversible logic:** *Maturity ~3–4 (in niche).* Superconducting digital tech (RSFQ/AQFP) has functioning prototypes – e.g. a 64-bit SFQ processor (demonstrated under DARPA’s program) and the 48k-JJ circuit[27]. These show fast progress (approaching Level 4 for certain niche computing like quantum annealers or specific accelerators). But as a general CMOS replacement, they are held back by infrastructure (cooling) and have not entered mainstream products. Reversible computing remains theoretical, though experiments indicate it’s within reach of superconducting tech[7][29] (yet no practical reversible CPU exists).

**Aggregation:** Since these approaches aim at the *same functionality* (improving digital logic performance/efficiency) and could be combined in future chips, we consider the **average maturity ~3**. The *overall ART* is at **lab prototype stage**: we have convincing demonstrations that break CMOS limits (proving plausibility), but **no commercial-ready device** yet. To reach Level 4, we would need, for example, a prototype processor or sensor node built with beyond-CMOS transistors that clearly outperforms a silicon equivalent *and* is close to manufacturable. Evidence missing for Level 4 includes: **high-volume reliability data, standard EDA integration, cost analysis, and commitments to productize** (e.g. a foundry announcing a post-CMOS node). Current efforts are promising but still in the R&D pipeline, justifying the maturity score of **3**.

## ART 02.011 Quantum Computing Platforms

### 1. ART extraction

**A) Primary capability** – Quantum computing platforms promise **massively parallel computation via quantum superposition/entanglement**, exploring vast solution spaces faster than classical supercomputers for certain problems (e.g. combinatorial optimization, high-dimensional pattern search, quantum system simulations). They leverage interference among many quantum states to perform calculations that scale beyond classical capabilities. These platforms also **integrate quantum processors with classical infrastructure**, functioning as specialized accelerators accessible through standard software interfaces (e.g. cloud APIs) so that users can run quantum algorithms remotely on complex problems that are infeasible to brute-force classically.

**B) Key sub-components or variants** – Multiple hardware approaches are being pursued for qubit implementation, including:

- **Superconducting qubits (circuit QED):** nano-fabricated Josephson junction circuits operating at ~10–20 mK in dilution refrigerators, controlled by microwave pulses (e.g. IBM, Google devices). This approach offers fast gate speeds and is currently the most mature in qubit count (tens to hundreds of qubits).
  - **Trapped-ion qubits:** individual ions confined in electromagnetic traps (ultra-high vacuum) and manipulated with laser or RF pulses. These qubits have long coherence and high fidelity (extremely low error rates) and flexible connectivity (e.g. IonQ, Quantinuum systems).
  - **Photonic qubits:** single photons or squeezed light states traveling through optical circuits of beam splitters, phase shifters, and detectors. Photonic processors operate at room temperature and naturally interface with fiber networks (e.g. Xanadu's photonic chips), and have demonstrated specialized sampling tasks leveraging many-mode interference.
  - **Topological qubits:** emerging approach encoding qubits in exotic quantum states (e.g. Majorana zero modes in topological superconductors) that are inherently protected from certain errors. This is pursued by research teams (e.g. Microsoft Station Q) with the goal of greatly improved stability, though it remains at a nascent experimental stage.
  - **Semiconductor spin qubits:** electron or nuclear spins in quantum-dot devices on silicon or GaAs chips, controlled by gate electrodes similarly to transistors. This leverages mainstream CMOS fabrication for potential scalability (e.g. Intel and academic groups have 2–6 qubit prototypes), though currently with smaller qubit counts and challenging control crosstalk.
- (Additionally, all platform variants require)\* a classical control stack\*\*** (high-speed electronics, cryogenics, lasers, etc.) to initialize, manipulate, and read out qubits with precise timing. The quantum processor is tightly integrated with classical CPUs/FPGA controllers for real-time feedback, error correction circuits, and a software layer (quantum compilers, schedulers, etc.) that translates high-level programs into low-level pulses.

**C) Maturity indicators** – Evidence of progress toward a viable quantum computing platform would include:

- **Demonstrations of quantum advantage:** clear experimental proof that a quantum

processor can solve a well-defined task faster than the best classical algorithms on the world's fastest supercomputers. (E.g. random circuit sampling or boson sampling experiments showing orders-of-magnitude speedups.) Such results bolster plausibility that these machines indeed access a computational regime beyond classical reach.

- **Scaling of qubit count and quality:** prototypes moving from few-qubit demos to devices with tens or hundreds of qubits while maintaining high coherence times and high gate fidelities. Key metrics include two-qubit gate error rates below the ~1% (or even ~0.1%) level, and system-level measures like quantum volume or circuit depth achieved. Increasing qubit connectivity (or modular linking of processors) and improved fabrication yields are also important for scalability.

- **Quantum error correction milestones:** evidence that logical (error-corrected) qubits can outperform physical qubits. For instance, demonstrations of encoding a logical qubit in many physical qubits and achieving a lower error rate than a single qubit, or creation of multiple logical qubits with basic operations. Successful error correction is a strong sign that the platform can eventually scale to fault-tolerant, large computations.

- **Prototype integration and field trials:** quantum computers operating outside of a single lab setting – e.g. deployed in data center environments or integrated with supercomputing facilities. Early **cloud services** (such as IBM Quantum or Amazon Braket) giving remote access to quantum hardware, or on-premises installations (in national labs or industry R&D centers), indicate progress toward practical use and reliability (cooling, control electronics, uptime) in real-world conditions.

- **Growing ecosystem & investment:** multiple well-funded companies and government programs racing to build better quantum processors, indicating that the technology has moved beyond a lone research curiosity. Evidence of substantial private and public R&D investment, startup commercialization (some companies going public or selling services), and collaborations (consortia, roadmaps, standardization efforts) all point to increasing maturity and confidence in eventual payoff.

- **Initial end-user applications or partnerships:** instances where quantum computers (even with their current limitations) are applied to non-trivial problems in science or industry via pilot projects. For example, using a quantum processor to explore drug molecule interactions, optimization in finance, or secure communications, in partnership with domain experts. Also, dedicated facilities (e.g. a quantum computer installed for healthcare research) suggest that early adopters see enough promise to invest in on-site hardware and workforce training.

## 2. Evidence (10–20 recent, reliable sources)

3. **IBM Unveils 433-Qubit Osprey Chip** – Charles Q. Choi (*IEEE Spectrum*) – Nov 2022. (**Peer-reviewed tech magazine news**) – IBM demonstrated a 433-qubit superconducting processor (“Osprey”) – more than **3× the qubit count of its 127-qubit predecessor** – suggesting they remain on track for a >1000-qubit device the following year<sup>[1][2]</sup>. To achieve this scale, IBM introduced a multi-layer wiring and cryogenic packaging design that protects fragile qubits and significantly increases control signal density. Notably, the new system can **control >400 qubits per rack of electronics (versus ~40 qubits per rack previously)** thanks to custom cryo-CMOS controllers<sup>[3]</sup>, highlighting engineering progress in scaling up quantum processors. (*This indicates the feasibility of building large quantum machines and a roadmap toward “quantum-centric supercomputers.”*)

4. **Suppressing quantum errors by scaling a surface code logical qubit** – *Google Quantum AI (Nature)* – Feb 2023. **(Peer-reviewed research)** – Google’s team showed the first **experiment where a larger quantum error-correcting code outperformed a smaller code**, a critical proof of concept for fault-tolerance. Using a **72-qubit superconducting chip**, they implemented a distance-5 surface code (49 physical qubits) and measured a logical error rate of **~2.9% per cycle**, slightly better than the ~3.0% per cycle for a distance-3 code (17 qubits) on the same device[4]. In other words, adding qubits *reduced* the error – a milestone indicating their physical qubit fidelity is above the threshold required for error correction[5]. *This result demonstrates plausibly that quantum computers can be scaled with manageable error rates, as the logical qubit’s performance improved when more qubits were used for encoding, something essential for building larger, reliable quantum processors.*
5. **Accelerating Towards Fault Tolerance: Unlocking 99.99% Two-Qubit Gate Fidelities** – *IonQ Inc., technical blog* – Oct 2025. **(Preprint/tech report by industry)** – Trapped-ion startup IonQ announced it has achieved **99.99% two-qubit gate fidelity** (“four nines”) on its latest system[6] – the highest reported to date. This landmark crosses a key error threshold for practical quantum error correction, and IonQ did so with a novel technique avoiding slow ground-state cooling, thus maintaining speed[6][7]. Such ultra-high fidelity gates reduce logical error rates by orders of magnitude, directly supporting the feasibility of scaling to larger, fault-tolerant quantum computers. *(This provides strong evidence of technical plausibility – a solution to what was a blocking error-rate problem – and indicates maturity as IonQ and others now target system scaling with these reliable gates.)*
6. **Quantinuum 56-Qubit System Breaks Benchmark** – *Quantinuum (press release)* – June 2024. **(Industry press, experimental result)** – Quantinuum (formed by Honeywell & Cambridge Quantum) unveiled a **56-qubit trapped-ion quantum computer (H2-1)** that achieved a **random circuit sampling task 100× faster** than Google’s 2019 “supremacy” experiment[8]. Crucially, this device combines relatively high qubit count with **“three nines” fidelity (99.9% two-qubit gate fidelity across all pairs)**[9] – a first in any quantum system – enabling record system-level performance. They also demonstrated the creation of **4 logical qubits with error correction** on this machine[9], showing that both scale and error rates have progressed to where fault-tolerant techniques are beginning to work. *(This illustrates rapid progress in the ion-trap approach, with a competitive, well-capitalized actor achieving both quantum advantage and steps toward error-corrected qubits in a commercial device.)*
7. **Xanadu’s Borealis Photonic Quantum Advantage** – *L. Madsen et al., Nature & Photonics Spectra summary* – June 2022. **(Peer-reviewed experiment + industry news)** – Canadian startup Xanadu demonstrated **quantum computational advantage** using a photonic processor called *Borealis* with **216 squeezed-light qubits**. The machine generated outputs from a Gaussian boson sampling problem in **36 μs, whereas the best classical supercomputer would take an estimated 9,000 years**[10] – a  $\sim 10^7$  speedup. Importantly, Borealis is fully programmable in its interferometer configuration and was made **publicly accessible via cloud** (Xanadu Cloud/AWS), making it the **first photonic quantum computer to achieve advantage available to outside users**[11][12]. *This provides evidence that photonic approaches, though less mature in general-purpose algorithms, are scientifically feasible and can be integrated into cloud platforms, supporting the ART’s plausibility (through a specialized task) and hinting at a future where such photonic modules might be part of quantum data centers.*
8. **Eight-Qubit Topological Quantum Processor (Majorana qubits)** – *Microsoft & UCSB (Nature paper via Phys.org)* – Feb 2025. **(Peer-reviewed & institutional press)** – A team from Microsoft and UC Santa Barbara announced the first-ever **topological quantum computing device**: an 8-qubit chip using **Majorana zero modes** in a superconducting heterostructure[13]. This

proof-of-concept “Majorana 1” processor demonstrated the creation and control of Majorana-based qubits, effectively **observing a new topological superconducting phase** that shows the predicted stability (distinct lifetimes for topological qubit states)[14]. While only a small prototype (described as an “embryo” of a quantum computer), it marks a *major scientific milestone* – proving the topological qubit approach is experimentally real and can perform quantum operations quickly and accurately[14]. *This evidence underscores the plausibility of eventually achieving inherently fault-tolerant qubits; however, the topological platform is clearly behind other approaches in maturity (still at lab demonstration stage, though backed by a major tech company’s long-term effort).*

9. **Full control of a six-qubit quantum processor in silicon** – S. Philips et al., QuTech/Delft (Nature) – Sept 2022. **(Peer-reviewed experiment)** – Researchers at QuTech (Netherlands) built a **6-qubit quantum chip in silicon** (using electron spins in quantum dots) and achieved **universal quantum logic with low error rates** on all qubits[15][16]. This is a record number of silicon spin qubits operated together; they implemented high-fidelity single- and two-qubit gates and improved state preparation and readout techniques, all in one device. Notably, they maintained performance as qubit count increased – **a major step toward fault-tolerant quantum computers using silicon fabrication**[17]. *This evidence shows the feasibility of an alternate, CMOS-compatible qubit technology and demonstrates that key hurdles (crosstalk, calibration, etc.) can be overcome for a multi-qubit silicon device. It also diversifies the quantum hardware ecosystem, indicating a broader race across platforms (industry + academia) to realize scalable qubits.*
10. **Jülich integrates a quantum computer into an HPC center** – FZ Jülich/QSolid (DataCenter Dynamics news) – Nov 2025. **(Industry news, deployment evidence)** – In Germany, a **10-qubit superconducting quantum prototype** developed by the QSolid consortium was **integrated into the Jülich supercomputing center’s infrastructure (JUNIQ)**[18]. In a late-2025 field test, the quantum machine was made available via the center’s cloud portal to external users for two weeks[19]. This represents one of the first instances of a quantum computer operating as part of a high-performance computing facility, allowing hybrid quantum-classical workflows. *This evidence demonstrates growing maturity: quantum hardware is leaving isolated labs and being treated as an operational resource in a data center environment, with collaborations (26 institutions in QSolid) focusing on system integration and user access. It also reflects government-backed efforts (EU/Germany) to build domestic quantum technology and link it with existing computing infrastructure.*
11. **IBM Delivers Quantum System One to Cleveland Clinic** – Cleveland Clinic Newsroom – March 2023. **(Industry press, deployment evidence)** – IBM and Cleveland Clinic unveiled the **first on-site, private-sector quantum computer**, an **IBM Quantum System One installed at a client location**[20]. This 127-qubit system is dedicated to healthcare research – the **first quantum computer in the world focused on a single industry application (biomedical)**[20]. The deployment is part of a 10-year Cleveland Clinic–IBM partnership to accelerate drug discovery and genomics via quantum computing. *This source indicates a significant maturity milestone: a quantum computer has moved from a vendor’s lab to a customer’s facility as a delivered product/service (albeit IBM-maintained). While still very expensive and early-stage, it shows that quantum computers are being treated as valuable tools for domain research, and that institutions are investing in quantum capabilities in anticipation of future advantages.*
12. **USTC’s Zuchongzhi-3: 105-Qubit Quantum Processor** – Pan et al., Physical Review Letters & USTC News – Mar 2025. **(Peer-reviewed physics result)** – A Chinese research team (USTC) announced Zuchongzhi-3, a **105-qubit superconducting processor** integrating 182 couplers, which performed quantum random circuit sampling **10<sup>15</sup> times faster than the fastest supercomputer**[21]. This greatly exceeded Google’s prior experiments and established the

strongest claimed quantum advantage to date in a superconducting system. The chip achieved **coherence times ~72  $\mu$ s and high fidelities (~99.9% single-qubit and 99.62% two-qubit gates)**[22], enabling an 83-qubit, 32-layer random circuit sampling that outpaced the best classical simulation by *15 orders of magnitude*. The team also reported implementing a **distance-7 surface code** on this device as a test toward quantum error correction, with plans to scale to distance-9 and -11[23]. *This provides evidence of both scientific and engineering maturity: USTC has reached 100+ qubit scales with performance near error-correction thresholds, and they are now focusing on error mitigation. It also highlights global competition – multiple countries’ teams (China, US, EU) have built cutting-edge quantum processors – a hallmark of a maturing field.*

### 13. Maturity score (1–7) and reasoning

#### Proposed Maturity Score: 5 (out of 7).

**A) Justification:** Quantum computing platforms as described are **beyond proof-of-concept (Level 3)** and even beyond a single functional prototype demonstration (Level 4); they are now in the **early competitive development stage (Level 5)**. Multiple well-funded players (IBM, Google, Amazon, Intel, Microsoft, IonQ, Quantinuum, etc.) are **actively building and iterating on prototypes**, and there is a **clear race to scale up qubits and reduce errors**, backed by significant investment and rapid technical progress. The evidence above shows that **key feasibility hurdles have been overcome** – e.g. high-fidelity operations (99.9%+ gates[9][6]), some algorithms beating classical performance[8][10], and integration of quantum hardware into cloud and research workflows[20][19]. This means the field is no longer just exploratory science (Levels 1–3), but is moving toward engineering for scalability and real-world use (Level 5). Crucially, **multiple quantum computing firms now offer devices as a service** to external users, and even deliver systems to partners, indicating that we are *post-“proof of concept”* – consistent with Level 5 where well-capitalized actors compete to develop production-worthy prototypes. Recent roadmaps (IBM aiming for 1000+ qubits by 2025, etc.) and the formation of large consortia (EU Quantum Flagship, US National QIS programs) further underscore this fast-paced progress and commitment to commercialization.

**B) Why not a higher score?** The technology is *not yet at Level 6*, because **quantum computers are not broadly delivered products with growing customer demand** – they remain costly, specialized installations primarily used in research or as cloud-based demonstrations. For Level 6, we would expect routine delivery of quantum computers, significant cost reduction, and expanding practical applications. In reality, today’s quantum systems still have limited qubit counts (tens to a few hundred, often with no error correction), very high operating costs (cryogenics, vacuum, etc.), and they can only solve certain niche problems that are carefully chosen. There is **no wide adoption in industry yet** – rather, early adopters are testing the waters via partnerships and pilot projects. Additionally, fully error-corrected, large-scale quantum computers (needed for many envisioned applications) have *not* been realized; the evidence shows progress in error correction but logical qubits are still error-prone and overhead is massive[4][9]. Thus, the **platform is not at the product maturation stage** where one could be deployed like classical computers with “increasing amounts” and ROI – it’s best seen as entering the late-prototype/early-adoption phase.

**C) Sub-component analysis:** The overall ART “Quantum Computing Platforms” encompasses several hardware approaches at slightly different stages, but their **functional goal is the**

**same (accelerating computation via quantum mechanics)**, so we assess maturity in aggregate by the leading edge. The **most advanced implementations (superconducting and trapped-ion)** merit a Score 5: for example, IBM and Google’s superconducting qubits have achieved quantum advantage experiments and are rapidly scaling devices[1][22], and IonQ/Quantinuum’s ion-trap systems boast record fidelities and have commercial cloud access[6][8]. These platforms have moved from lab experiments to multi-qubit prototypes used by external users, aligning with the “production prototype under intense development” description of Level 5. **Photonic quantum computers** have demonstrated a specialized advantage (boson sampling) and are available via cloud (Xanadu), but have not shown general-purpose algorithms or error correction – they are slightly earlier in maturity (around Level 4) yet do not fundamentally change the overall score since photonics targets similar use-cases and is racing forward as well[12][10]. **Emerging approaches like topological qubits** are far behind (Level 2–3, still proving basic viability[13]), but these serve as long-term bets and are not required for near-term quantum computing success given progress in more mature modalities. Considering all threads, the field’s center of gravity is solidly at Level 5 – multiple prototypes exist solving previously intractable tasks and attracting competition – but **has not yet reached Level 6** where quantum computers are a practical commodity delivered to many customers. Therefore, **Score 5** best represents the current maturity: *a disruptive technology in the late-prototype stage with active competition and clear momentum toward commercialization, but still awaiting its first broadly practical products and scalable manufacturing breakthroughs.*

## ART 02.012 Photonic and Optical Computing

### 17. ART extraction

18. *Primary capability* – **Light-based computation and data movement:** Using photons instead of electrons to perform computing operations and chip-to-chip interconnect, aiming for **vastly higher bandwidth and lower energy/heat** than electronic circuits[1][2]. This allows processing more data with less latency and within tighter power/cooling limits than conventional electronics.

19. *Key sub-components & variants:*

- **Chip-scale photonic processors/cores:** Specialized optical units (e.g. matrix-multiplication “tensor cores”) performing neural-network computations or optimizations via interference, modulation, and wavelength multiplexing[1][3]. Often hybrid designs: photonics handle large parallel linear operations while electronics provide control and non-linear functions.
- **Ultra-dense optical interconnects:** Integrated photonic links (waveguides, fiber, modulators) connecting CPUs, accelerators, and memory with extremely high bandwidth (>1–4 Tb/s) at low latency and distance-independent energy cost[2][4]. This includes *in-package optical I/O chiplets* and co-packaged optics for next-gen data centers, enabling disaggregated memory and processor pools.
- **Hybrid electro-optic modules:** Packaging of photonic chips with CMOS control/logIC. Electronics handle programmability, storage, and precise logic; optical components accelerate data-heavy operations and communications. Examples include 3D-integrated packages with multiple photonic and electronic dies interconnected for AI acceleration[5].

20. *Maturity indicators (evidence to look for):*

- **Lab demonstrations of core feasibility:** e.g. optical matrix-multiplies, photonic neural nets or optical Ising solvers outperforming electronic baselines, with metrics like TOPS/W or latency showing a clear advantage[6][7].
- **Integrated prototypes meeting application needs:** Complete photonic computing systems solving real AI tasks (image recognition, NLP, etc.) with accuracy close to digital and reasonable precision (4–8 bits analog)[8]. Prototype optical interconnects moving real data between chips in HPC setups[4].
- **Transition toward productization:** Proof-of-concept **optical processors and interconnects operating in practical environments**, e.g. installed in supercomputers or edge devices, or demonstrated in standard form factors (PCIe cards, chip packages)[2]. Signs of **well-funded startups and industry players** (multiple companies, large investments, partnerships) racing to commercialize optical computing components.
- **Manufacturing and integration progress:** Advances in photonic chip fabrication (silicon photonics, new materials) enabling scale and reliability – e.g. foundry-compatible processes for on-chip lasers or non-volatile optical memory[9]. Roadmaps from industry consortia or labs outlining clear performance targets and volume deployment within a decade[10].
- **Early deployments and shipments:** Evidence of optical computing hardware being **delivered to pilot customers** or integrated into existing systems, with improving economies of scale. For example, optical I/O modules shipping with FPGAs or AI systems, and photonic co-processors available via cloud or as appliances (even if in limited beta).

21. **Evidence (10–20 recent, reliable sources)**

22. **Photonic AI processor runs real AI models (Nature, 2025)** – Sufi R. Ahmed et al. (*Lightmatter Inc.*), peer-reviewed article, Apr 2025. A silicon photonic processor (6-chip 3D-integrated package with ~50 billion transistors and 1 million photonic components) was demonstrated to **run state-of-the-art neural networks (ResNet image classifier, BERT language model, DeepMind’s Atari RL)** with accuracy **approaching 32-bit digital electronics**[8][5]. It achieved 65.5 trillion ops/sec at ~80 W (1.6 W optical power) – a major milestone proving that photonics can handle complex AI workloads with performance and precision near conventional GPUs, marking a “substantial step towards post-transistor computing”[8].
23. **64×64 photonic computing chip beats GPU in latency (Nature, 2025)** – Shiyue Hua et al. (*Lightelligence & Stanford*), peer-reviewed article, Aug 2025. This work built a **highly integrated 64×64 optical matrix accelerator** (~16,000 photonic components on-chip) for solving an Ising optimization (MaxCut) problem. It attained **~7.6-bit analog computation accuracy** and achieved the solution **in 2.7 μs, over 300× faster latency than a high-end GPU (798 μs)** on the same task[6][11]. This validates that large-scale silicon photonic circuits can be reliably fabricated and can outperform electronic computation in speed for specific workloads, using **commercial silicon photonics technology** and hybrid electronic control[1].

24. **“Taichi” photonic chiplet – 160 TOPS/W AI engine (Science, 2024)** – Zhihao Xu et al. (Tsinghua University), peer-reviewed article, Apr 2024. A Chinese research team demonstrated “Taichi”, a **large-scale photonic neural network chiplet** that achieved **160 Tera-OPS per Watt energy efficiency** and **~879 Tera-MACs/mm<sup>2</sup> area density**, exceeding state-of-art electronic AI chips by 2–3 orders of magnitude in those metrics[12]. Uniquely, it implemented an optical network with **billions of neurons** (via diffraction and interference in a 64×64 input/output optical array) and successfully performed complex tasks: e.g. **1,623-category image classification (91.9% accuracy)** and **100-class mini-ImageNet classification (87.7% accuracy)** – the first time an optical chip tackled thousand-class vision tasks[13][12]. This massive scalability and efficiency showcase the plausibility of photonic processors to go beyond simple demos toward “beyond-billion-neuron” AI models in the future.
25. **All-optical neural network with on-chip training (Nat. Photonics, 2024)** – Farzin Ashtiani et al. (Univ. of Pennsylvania), peer-reviewed article, Dec 2024. Demonstrated a **single-chip photonic deep neural network** that not only performs inference but also supports *in situ* training (forward-only training method). The silicon photonic chip, containing dozens of programmable interferometers, achieved **92.5% accuracy on classification tasks** and could execute an inference in **only 410 picoseconds** optical latency[14]. This result shows that integrated photonic circuits can reach competitive accuracy on real datasets and operate at **nanosecond-scale inference speeds**, albeit currently on smaller-scale networks – a promising path to ultrafast, low-energy AI inference.
26. **Optical AI accelerator for wireless edge (Science Advances, 2025)** – Dirk Englund’s group (MIT), peer-reviewed article reported via MIT News, Jun 2025. Researchers built a photonic hardware accelerator aimed at 6G wireless signal processing. The **optical chip classifies radio signals in nanoseconds**, achieving about **100× faster throughput than the best digital signal processor**, while still reaching ~95% classification accuracy[7]. The device is also smaller, lighter, and more energy-efficient than conventional AI edge hardware[7]. This *edge photonic processor* illustrates the feasibility of deploying optical computing beyond the lab – in this case to enable real-time spectrum management or potentially autonomous vehicle sensors – where its **speed-of-light parallelism yields tangible system-level benefits**.
27. **Analog optical computing for AI and optimization (Nature, 2025)** – Kirill Kalinin et al. (Microsoft Research Cambridge et al.), peer-reviewed article, Sep 2025. This work introduces an **analog optical computer (AOC)** that combines **free-space 3D optics with analog electronic feedback** to solve both neural network inference and combinatorial optimization without digital conversions. The system uses a **fast 20 ns optical/electronic loop** where optical components handle large matrix-vector multiplications and electronics apply nonlinearities and feedback[3]. In prototypes, it successfully performed image classification, medical image reconstruction, and even a financial transaction optimization problem on the same hardware[15]. Built largely from scalable, “consumer-grade” components, this AOC achieved significant speed-ups and highlights a co-design approach (algorithm and hardware) to overcome noise and precision issues in analog photonic computing[15][3]. Its demonstration of a *single platform tackling AI and NP-hard optimization* underscores the versatility and plausibility of optical analog computing for future ultra-efficient processors.

28. **4 Tb/s optical I/O chiplets in FPGA (Ayar Labs & Intel, 2023)** – *Ayar Labs press release, Nov 2023 (Supercomputing '23 showcase)*. Ayar Labs demonstrated an **Intel Agilex FPGA with two “TeraPHY” optical I/O chiplets integrated**, delivering an aggregate **4 Tbps bidirectional bandwidth** (2×4 Tb/s) via 64 optical channels per chiplet[2]. The optical FPGA achieved **5× the I/O bandwidth of conventional electric links, with <5 pJ/bit energy and only ~5 ns latency** per optical hop[2]. This is a concrete industry result showing that in-package photonic interconnects can drastically boost throughput while reducing latency and power. Notably, the optical links operated error-free over fibers and were powered by compact multi-wavelength semiconductor laser modules – proving maturity in the **packaging and integration** of photonics with standard electronic chips for HPC/AI use. (The company noted that optical I/O “has the maturity and manufacturability” for upcoming high-performance systems[16].)
29. **Intel’s co-packaged optical interconnect demo (Intel, 2024)** – *Intel Integrated Photonics Group, technical press release, OFC Mar 2024*. Intel reported the **first fully integrated optical compute interconnect (OCI) chiplet** co-packaged with a CPU, running live data[17]. The prototype optical I/O chiplet carried **64 channels × 32 Gbps each (≈2.0 Tb/s per direction)** and supported links up to 100 m fiber length[4]. This breakthrough enables future CPUs/GPUs with optical I/O for memory pooling and resource disaggregation, far exceeding the reach and bandwidth density limits of copper—“boosting bandwidth, reducing power consumption and increasing reach” for AI systems[18][4]. Intel’s demo underscores that major industry players are actively de-risking the manufacturing (co-packaging, alignment, etc.) and proving out reliability of optical interconnects in realistic environments, a critical step toward commercialization in data centers.
30. **Heterogeneous photonic integration with non-volatile memory (Nat. Commun., 2024)** – *Maoliang Wei et al. (Zhejiang Univ. & Westlake Univ., China), peer-reviewed article, Mar 2024*. This study tackled a key fabrication challenge: integrating new materials for optical computing on a CMOS photonics platform. The team developed a foundry-compatible process (“zero-change” backend integration) to add **chalcogenide phase-change materials (PCMs)** into silicon photonic chips[19][20]. They successfully incorporated two PCMs (Sb<sub>2</sub>Se<sub>3</sub> and GSST) to create **non-volatile optical tuning devices** that require **no power to hold state**. Using these, they realized compact optical switches and attenuators with multi-bit precision – e.g. microring filters with **>5-bit intensity control and broadband attenuators with >7-bit depth**, as well as a 48% reduction in power for trimming a Mach-Zehnder switch thanks to non-volatile phase correction[9]. This is important evidence of progress in **optical memory and reconfigurability**: it shows that high-precision optical weights or settings can be built and *monolithically fabricated* at scale, addressing bottlenecks of power-hungry tuning and enabling programmable photonic circuits for computing.
31. **Silicon photonics roadmap highlights computing era (Perspective, 2024)** – *Sudip Shekhar, Wim Bogaerts et al., Nature Communications perspective, Jan 2024*. Leading researchers outline the next generation of silicon photonics, noting that after revolutionizing datacenter transceivers, the field is now entering an era of **Large-Scale Integration (LSI)** with **500–10,000+ photonic components per chip**[10]. They cite emerging applications like **photonic computing, switching, and LiDAR** as drivers for this complexity, and point out that even **VLSI prototypes (>10k components) have been demonstrated** in labs[10]. Crucial challenges identified include integrating on-chip light sources, improving photonic packaging, and co-designing

electronics–photonics for better yield and performance[21][22]. This authoritative roadmap confirms strong academic and industry interest in optical computing, and that the community is systematically addressing the **fabrication and integration bottlenecks** (laser integration, CMOS-foundry compatibility, packaging) to move from millions of units (transceivers) to “*billions of units shipped*” in photonics over the coming decade[23] – a scale which would imply mainstream adoption of technologies like photonic computing accelerators and optical I/O.

### 32. Maturity score (1–7) and reasoning

**Proposed Maturity Score: 5** (out of 7).

**Justification:** Photonic/optical computing has advanced beyond fundamental lab demos (levels 2–3) to **full system prototypes and early commercial-stage development**, but has not yet reached widespread product deployment. The evidence shows multiple **functioning proof-of-concept systems (level 4)** – for example, *photonic AI chips performing real tasks with competitive accuracy and speed*[8][7], and *integrated optical interconnects meeting performance targets in realistic settings*[4]. These prototypes clearly achieve benefits (orders-of-magnitude speed or efficiency gains) beyond what traditional electronics offer, satisfying key functionality needed for commercialization (e.g. analog optical accelerators attaining nearly digital precision, or optical links delivering 5× bandwidth at fraction of power)[6][2]. Importantly, the field now features **several well-capitalized actors and active competition**: multiple startups (Lightmatter, Lightelligence, Ayar Labs, etc.) and large firms (Intel and others) are racing to develop production versions of optical computing hardware, supported by significant funding and partnerships. This corresponds to level 5, where **post-PoC development is rapid and moving toward product prototypes**. For instance, Lightmatter’s 6-chip processor and Lightelligence’s 64×64 optical accelerator, both published in 2025, indicate that **production-worthy designs are in late-stage testing**[8][1]. Likewise, optical I/O solutions are **already being showcased in standard platforms (FPGA, CPU packages)** and slated for integration into next-gen data center hardware[24][17], with some initial shipments to early customers reported. This momentum goes beyond isolated lab research, underscoring that the technology is on the cusp of commercialization.

*Why not a 6 or 7?* Full commercial rollout (level 6–7) is *not yet* achieved. While prototypes exist, **broad customer delivery and scaling are just beginning**. There is no evidence yet of optical computing hardware shipping in volume or being widely adopted in production data centers – current deployments are limited to pilot installations or specific demo units. Key manufacturing and cost challenges remain (e.g. mass-producing photonic chips with high yield, integrating lasers economically, developing a software ecosystem), and no **off-the-shelf optical general-purpose processor** is commercially available as of 2025. In short, the technology has proven its merit (ruling out levels 1–3 decisively) and attracted serious investment (well beyond level 4), but **needs further engineering and scaling effort to move into routine, large-scale use**. Reaching level 6 will require demonstrating reliable volume production and delivering devices to many customers with decreasing costs – likely a few years away.

*Sub-component outlook:* Within this photonic computing bundle, **optical interconnects** may be slightly more mature than photonic processors. High-bandwidth optical I/O is already **sampling to industry partners** and on a roadmaps for near-term integration in AI systems[18][24]. One could argue optical interconnect tech is approaching level 6 (initial

products delivered, e.g. co-packaged optics for switches). Meanwhile, **photonic computing accelerators** (for AI/ML, etc.) are at a solid proof-of-concept stage, around level 4–5, with functional prototypes but only limited early-user access. Considering the combined impact, we assign an overall **score 5**, reflecting that *most pieces of the photonic computing stack have left the lab and are in the late prototype/early-product-development phase*. This score acknowledges the significant recent progress (multiple demonstrations solving real problems, multi-actor investment), while recognizing that the **technology as a whole has yet to fully cross into widespread productization**, which will be the hallmark of level 6.

## ART 02.013 Next-Gen Memory & Storage

### 81. ART extraction

82. **Primary capability:** Enable vastly higher-density and longer-lasting data storage, allowing computers to keep more data “live” in non-volatile memory. This includes storage media that retain data with power off, endure far more write cycles than today’s flash, and even perform data processing directly where data is stored (minimizing data movement).

### 83. Key sub-components/variants:

- *Resistive & magnetoresistive memories (ReRAM, MRAM):* Non-volatile RAM using resistive changes or magnetic tunneling to store bits, aiming to combine DRAM-like speed with NAND-like persistence.
- *Advanced NAND flash:* Continued scaling of flash memory (3D structures with more layers, multi-bit cells) for higher density and I/O performance (e.g. 200+ layer TLC/QLC NAND).
- *DNA-based storage:* Encoding digital data in synthetic DNA strands for extreme density and millennial longevity; primarily for “cold” archives due to high latency.
- *Molecular/DNA computing:* Performing in-storage operations (like search or pattern matching) via biochemical reactions on DNA or other molecular data stores.
- *Processing-in-memory/storage:* Architectures that integrate compute logic into memory or storage devices (e.g. in-memory computing, computational storage drives) to process data in-place.

84. **Maturity indicators:** Evidence of **lab prototypes and demos** (e.g. storing/retrieving real data in DNA, or resistive memory arrays meeting endurance targets); **proof-of-concept integrations** (e.g. memory devices embedded in standard chips, or storage drives with in-situ processing); **field trials or initial products** (e.g. new NVM used in commercial systems); **multiple industry players investing** (competing startups, foundry offerings, alliances); and **roadmaps or standards efforts** (signaling path to manufacturing scale and market adoption).

### 85. Evidence (10–20 recent, reliable sources)

86. **DNA storage search demo (iPRES 2023)** – L. Provencher et al., Univ. of Illinois (conference short paper, 2023). Demonstrated DNA-based data storage and in-memory search: encoded images and full literary texts into DNA and successfully queried a specific word across multiple stored works[1]. This shows the feasibility of **molecular storage** combined with simple **DNA-based computing**, retrieving data subsets without reading the entire archive – a key step toward in-storage processing.

87. **Massively parallel DNA storage search (Catalog, 2022)** – Catalog Technologies (press release via GlobeNewswire), 12/2022. Reported a breakthrough in DNA computing: encoded ~17,000 words of Shakespeare into DNA “in a few minutes” on a

microfluidic DNA writer, then performed a chemical **keyword search** that retrieved all occurrences of a query word[2]. Notably, the search time stayed constant even when scaling to 200k words and is projected to remain ~constant up to 100 million words[3]. This underscores DNA storage's **massive parallelism** – searching an exabyte-scale archive via chemistry – and demonstrates a proof-of-concept for **DNA as both storage and compute medium** (albeit with slow absolute speeds).

88. **SNIA DNA Data Storage Tech Review (2025)** – *DNA Data Storage Alliance (industry report, SNIA, 2025)*. *Authoritative status review*: Confirms that **throughput and automation** are the main hurdles for DNA storage. Current write speeds are on the order of 0.001 MB/s (~100 MB/day), vastly slower than tape or SSD, but **advances in DNA synthesis parallelism are on track**. In 2022, Twist Bioscience unveiled a chip with ~100 million synthesis spots (writing ~1 GB per run), and projections foresee **100 billion parallel synthesis features by ~2027**, reaching “commercially relevant” data rates[4]. This roadmap – backed by the IARPA program – bolsters the plausibility of DNA archives, while emphasizing that significant manufacturing innovation (e.g. array chips, automation of fluid handling) is required.
89. **Infineon & TSMC embed RRAM in MCUs (2022)** – *Infineon & TSMC (joint market news, 11/2022)*. *Industry prototype announcement*: The next-gen Infineon AURIX™ TC4x automotive microcontrollers will use TSMC's embedded **Resistive RAM (RRAM)** technology at 28 nm, replacing embedded flash[5]. RRAM was chosen for its scalability beyond 28 nm and its reliability: it allows byte-level writes (no bulky erase cycles) and offers **endurance and retention on par with flash** memory[6]. Early samples of the 28 nm RRAM-based chips were slated for customer delivery by end of 2023[7]. This marks a significant step toward commercialization of **ReRAM**, with a top-tier chipmaker and foundry validating it for safety-critical, high-volume applications (automotive), thereby demonstrating both technical feasibility and industry commitment.
90. **Review – Emerging NVM in industry (Hellenbrand et al. 2024)** – *Cambridge University (peer-reviewed in MRS Communications, accepted 10/2024)*. *Survey of industrial progress*: Finds that **STT-MRAM and oxide ReRAM are the frontrunners** among emerging non-volatile memories for embedded use, with several implementations “very advanced” and aiming to **replace embedded flash**[8]. In contrast, Phase-Change Memory and FeRAM are “less available” as commercial products[8]. The review collates concrete performance achievements: e.g., **Everspin's 1 Gb STT-MRAM** has  $10^{10}$  cycle endurance and is qualified in 28 nm and 22 nm nodes, and **Avalanche Technology's MRAM** reached  $>10^{14}$  cycles and  $10^3$ -year retention at 85 °C in 22 nm chips[9][10]. It also notes that multiple foundries (GlobalFoundries, TSMC, Samsung) now offer embedded MRAM/RRAM options. This broad evidence base shows that the **materials and device challenges (endurance, retention, scaling) are largely solved** for MRAM/ReRAM, and these memories have entered the pilot production and product integration phase.
91. **IBM adopts MRAM in enterprise storage (2024)** – *Everspin Technologies & IBM (press release, 05/2024)*. *Product integration evidence*: IBM's latest FlashCore Module 4 (high-end SSD for IBM FlashSystem arrays) incorporates Everspin's **1 Gb STT-MRAM** as a persistent write buffer[11]. The MRAM, with a DDR4 interface, delivers **2.7 GB/s read/write throughput** with “instant non-volatility,” ensuring no data loss on power failure[12]. IBM's adoption of MRAM – displacing supercapacitor-backed DRAM in the

array's design – underscores that emerging memory has matured enough for **mission-critical, shipped products**. It provides real-world validation of MRAM's speed/endurance advantages for low-latency storage and indicates scaling to gigabit-class densities.

92. **Samsung SmartSSD (2nd Gen, 2022)** – *Samsung Electronics & AMD (press release, 07/2022). Computational storage in action:* Introduces Samsung's second-generation SmartSSD, a SATA SSD with an integrated Xilinx (AMD) FPGA. This **in-situ processing** drive can offload data-intensive tasks (e.g. database scans, video transcoding) to the storage device itself. In tests, it cut query processing time by >50%, with **70% lower energy and 97% lower host CPU usage** compared to a conventional SSD performing the same task[13]. Notably, Samsung confirms the **1st-gen SmartSSD (2020)** has already been delivered to customers (e.g. video platform providers) and proven its value (CES 2021 Innovation Award)[14]. The 2nd-gen's improved onboard ARM cores and customer-programmable IP demonstrate increasing maturity. This is evidence that **compute-storage convergence** is leaving the lab: major vendors are standardizing it (Samsung is working with SNIA and NVMe bodies[15]) and customers are testing real workloads, validating the concept's practicality.
93. **Micron 232-layer 3D NAND in production (2022)** – *Micron Technology (press release, 07/2022). Advancing the incumbent tech:* Micron began **volume production** of the world's first 232-layer NAND flash in 2022, heralding it as a "watershed moment" proving that 3D NAND can scale beyond 200 layers in manufacturing[16][17]. This sixth-generation NAND achieves the industry's highest bit density and boosts per-chip read/write bandwidth by >75%/100% over the prior 176-layer node[18]. It also introduces architecture innovations (e.g. first six-plane NAND) for better parallelism. By shipping this flash in consumer SSDs and announcing data-center deployments, Micron demonstrated **continued viability of flash scaling**. This directly addresses the ART's motivation ("growth of digital data straining conventional storage") by extending NAND's density and energy efficiency within acceptable cost – an important *near-term* component of a next-gen memory hierarchy.
94. **Weebit Nano & SkyWater deliver ReRAM silicon (2022–23)** – *Weebit Nano & SkyWater Tech (joint announcement, 11/2022; follow-up news, 06/2023). Foundry qualification of ReRAM:* Startup Weebit and US foundry SkyWater **produced the first silicon wafers with embedded ReRAM** in late 2022, using a mature 130 nm CMOS process[19][20]. This was the *first ever* ReRAM integration in a production fab, achieved with standard tools and flows – a major milestone toward commercialization[21]. By mid-2023, the 256 Kb ReRAM macros (on demo chips with a RISC-V MCU and periphery) were fully qualified for reliability and offered to customers for SoC designs[22][23]. This evidence shows that **resistive memory IP is becoming fab-ready** for embedded use, enabling third-party chip designers to adopt it. It also highlights growing *competitive activity*: besides Infineon/TSMC, a second supplier (SkyWater/Weebit) is entering the market, which will help drive down risk and cost of ReRAM technology.

95. **Maturity score (1–7) and reasoning**

**Score: 5 (Proof-of-Concept to early prototyping stage).**

**A) Justification of score:** The collected evidence indicates that **multiple threads of "next-gen memory" have progressed beyond lab demonstrations (Level 3) into proof-of-concept prototypes (Level 4) and are now entering the production prototyping and early product phase (Level 5)**. In particular, **non-volatile memories like MRAM and ReRAM have working**

**prototypes meeting commercial requirements** – for example, embedded RRAM in 28 nm MCUs and 1 Gb STT-MRAM in shipping IBM storage systems – and **several well-funded actors (Infineon, Samsung, foundries, startups)** are actively investing in their development[6][11]. This clearly surpasses Level 3/4: the core technical feasibility has been proven (high endurance, retention, etc.), and the motivation for commercialization is validated by real use-cases (e.g. MRAM eliminating backup capacitors in storage[24]).

**Standardization efforts and competition** (multiple foundry IP offerings, industry alliances like the DNA Storage Alliance, SNIA computational storage group) further confirm a Level 5 scenario – progress is rapid and stakeholders are coordinating to ready these technologies for market[15][4].

Crucially, **the ART is a bundle** spanning very mature to still-nascent elements. On one end, advanced 3D NAND flash is *already* in volume production (a solid Level 7 for that component)[16], and novel storage-class memory like 3D XPoint had briefly reached market (Optane, 2017–2022) before economic factors led to its discontinuation. On the other end, **molecular/DNA storage is still at lab prototype stage** – automated DNA write/read cycles have been demonstrated[25], and even in-memory DNA search has been shown[2], but **throughput and cost are orders of magnitude from viability**, corresponding to roughly Level 2–3. The overall “next-gen memory stack” vision assumes integrating these layers, so its full realization depends on the **least mature link (DNA)** catching up in coming years.

Given this mix, a *Level 5* assessment reflects a **weighted average** of sub-technologies. **Persistent RAM (MRAM/ReRAM)** is nearing Level 6 (initial products and scaling plans) but not yet ubiquitous; **computational storage and in-memory processing** have seen proof-of-concept deployments (SmartSSD, PIM-enabled memory) in niche markets – again around Level 5. Meanwhile, **DNA storage/computing is at Level 3** at best, still needing a breakthrough in speed and cost to reach PoC viability[26][4]. As a whole, the field is best characterized as “*transiting from PoC to prototype*”, with strong momentum but not yet a broadly market-ready solution set. This rules out lower scores: the concept is far beyond theoretical (Level 1) or initial lab proof (Level 2) – we have functional devices and compelling demonstrations in multiple domains. At the same time, it is **not** at Level 6 because, aside from conventional flash, we don’t see wide customer uptake or economies of scale for most of these new memories yet (e.g., no **mass adoption of MRAM in consumer devices** so far, and DNA storage is not productized). Key evidence still missing for Level 6–7 would be: large-scale manufacturing ramp-ups, clear cost-per-bit competitiveness, and multiple vendors shipping interchangeable products (signifying a mature market). Over the next decade, we would expect to see precisely those developments as prototypes turn into commercial memory offerings.

#### **B) Sub-component breakdown:**

- **MRAM (magnetoresistive RAM):** *Maturity* ~6. Proven in logic-qualified processes (14–28 nm) with **billion-cycle endurance** and used as embedded NVM by foundries[27]. Everspin’s standalone MRAMs are shipping (the **IBM module use** is strong Level 6 evidence of “products delivered to customers”)[24]. MRAM enjoys **multiple suppliers (Everspin, Samsung, TSMC, etc.) and growing adoption**, pushing it toward early Level 6.
- **ReRAM (resistive RAM) & Phase-Change Memory:** *Maturity* ~4–5. They have cleared major technical hurdles (high-temperature retention, switching endurance) in research[28][29], and **first commercial integrations are underway** (Infineon’s RRAM MCU sampling in 2023,

Weebit/SkyWater’s qualified ReRAM IP)[7][20]. However, *volume production* and broad competition are just beginning – implying late Level 4 to Level 5. (Notably, Intel/Micron’s PCM-based 3D XPoint reached Level 6 in 2020 but was a single-supplier product and was discontinued, so PCM’s current commercial presence is limited.)

- **Advanced 3D NAND Flash: Maturity ~7.** This is in full mass production worldwide; multiple firms (Micron, Samsung, SK Hynix) compete on layer count and cell design. The **232-layer node** debut in 2022[16] and roadmap to 300+ layers show continued scaling. It’s a mature market with **economies of scale and rising demand**, characteristic of Level 7. (It’s included here as the baseline “bulk storage” layer that next-gen memories will augment, not replace, in the near term.)

- **DNA-based storage & computing: Maturity ~2–3.** Fundamental studies have validated the concept (e.g. kilobyte–megabyte data archives retrieved successfully, DNA logic operations performed in vitro)[25][2] – so it’s beyond mere theory. An **automated DNA storage device** was built in 2019[25], and recent demos by both academia and startups show improved integration (parallel synthesis, search-in-storage)[2][3]. Still, **no proof yet that it meets real-world speed or cost requirements** – current write/read is millions of times slower than magnetic/solid-state media, and costs are in the \$1000s per megabyte. This sub-area remains at early experimental stage (Level 2–3), needing significant engineering breakthroughs (which are expected over a 10–20 year horizon, per the ART description).

- **Compute-in-memory / computational storage: Maturity ~5.** Initial products exist (Samsung’s SmartSSD, AI-enabled memory like HBM-PIM samples) and **enterprise trials are validating the performance gains**[13]. Multiple big players (Samsung, AMD, Huawei, etc.) are investing, and standards groups are involved – indicating a transition from one-off demos to broader prototyping. The concept is proven beneficial (e.g. SmartSSD’s 50% query speedup[13]), but it’s not yet mainstream in data centers (no Level 6 scale deployment yet).

We assign an overall **Level 5** because the **functionality of the “next-gen memory” vision relies on combining these layers**, and at this point, some critical layers (and their integration software) are only in the proof-of-concept phase. In other words, the **value proposition spans diverse use-cases (fast cache, persistent main memory, archival store, in-situ processing)** that won’t be fully realized until *each* piece achieves product maturity. Thus, averaging the sub-scores (from ~3 for DNA to ~7 for NAND) yields a mid-level maturity. We chose Level 5 to reflect that **several of the technologies are in late R&D with clear commercial momentum**, even though the *complete revolutionary stack* will materialize over the coming decade. This score is supported by evidence of rapid progress and growing industry commitment, while also acknowledging that **further development and scaling investment** are needed to reach the next level (e.g. widespread adoption and cost reduction to challenge incumbent memories).

## ART 02.014 Molecular Computing

### 1. ART extraction

**A) Primary capability:** This ART envisions **molecular computing** platforms that perform information processing using chemical/biological reactions (e.g. DNA strand interactions) instead of electronic circuits. The key capability is **in-situ computation at the molecular scale** – encoding, storing, and transforming information via molecular concentrations, sequences, and reactions. This would allow **embedded logic within chemical or biological environments** (e.g. inside fluids, cells, or materials) where conventional silicon electronics cannot easily operate.

## B) Key sub-components/variants:

- **DNA/RNA strand-displacement circuits:** Dynamic networks of nucleic-acid strands and enzymes implementing logic gates and cascades in solution[1][2]. Variants include DNA-based neural networks and classifiers that perform pattern recognition and learning tasks purely with molecules[3][4].
- **Molecular logic in living cells:** Engineered genetic or protein circuits inside living cells or synthetic biomaterials that process multiple molecular inputs and produce functional outputs. Examples include protein-based logic gates in cells that respond to chemical signals with different actions (e.g. change cell orientation or gene expression)[5][6].
- **Microfluidic/”lab-on-chip” molecular processors:** Miniaturized devices (fluidic chips, reactors) that integrate molecular computing reactions with physical infrastructure. These use channels, compartments, and surface-bound components (like DNA origami “registers”) to execute multi-step computations faster and with automation[7][8].
- **Parallel DNA computing for data storage/search:** Techniques that leverage DNA’s massive parallelism to compute on data stored in DNA databases. For instance, DNA-based search algorithms can retrieve matches from DNA memory archives in parallel, scaling almost independently of data size[9][10].
- **Network-based biocomputation (molecular motor circuits):** An alternative model using biological nanomotors (proteins) and nanofabricated networks. Here, molecules like motor-propelled filaments explore physical channel networks to solve computational problems in parallel (e.g. pathfinding for NP-complete problems)[11][12].
- **Design automation and programming tools:** High-level languages, AI-assisted design platforms, and standard “molecular instruction sets” that allow researchers to **program molecular logic** without manual trial-and-error. Recent advances include automated DNA circuit design using AI/ML models trained on large libraries of circuit variants[13][14] and tools for error-correcting molecular encodings.

**C) Maturity indicators:** Evidence of maturity would include: **Multi-layer prototypes and proof-of-concept demonstrations** (e.g. multi-step logic circuits, molecular classifiers) in labs; **field trials or real-world applied demos** (such as diagnostic tests or control systems using molecular logic); **integration into usable devices** (microfluidic chips or kits performing molecular computation autonomously); **well-funded development efforts or startups** (competition among companies, dedicated consortia); **standardization of tools and workflows** (automated design software, repeatable processes); and signs of **progress toward practical performance** (e.g. improved speed, error correction, cost reduction, scalability to real data sizes) such that the technology moves from one-off experiments to robust prototypes.

## 2. Evidence (10–20 recent, reliable sources)

- **RNA Strand-Displacement Logic Circuits (Science Advances 2022)** – Schaffter & Strychalski (NIST) – Peer-reviewed paper (Mar 2022).  
*Demonstrated the largest and most complex molecular logic circuits to date using DNA/RNA strand displacement. Achieved multi-layer cascaded logic and signal amplification in a test-tube system, with circuit behavior accurately predicted by a simple model[1][2]. This showcases the feasibility of designing scalable molecular logic gates and suggests a path to circuits operable in living cells (by using RNA transcription to generate DNA strands in situ). It*

*proves the underlying computing principle in chemistry and addresses a key challenge of multi-step signal processing in molecular systems.*

- **DNA Neural Network with Supervised Learning (Nature 2025)** – Kevin Cherry & Lulu Qian (Caltech) – Peer-reviewed article (Sept 2025).  
*Showed that DNA molecules can autonomously perform supervised machine learning. A DNA-based neural network was trained to classify 100-bit binary patterns entirely in vitro, with molecular “weights” stored as DNA concentrations[3][4]. The system learned to correctly categorize new inputs after training, demonstrating pattern recognition and adaptive behavior emerging from DNA reactions. This result greatly expands plausibility by proving complex computational algorithms (like neural network learning) can be implemented in a wet molecular system, albeit at laboratory scale.*
- **Protein Logic Gate in Live Cells (Science Advances 2023)** – Jiaxing Chen et al. (Penn State) – Peer-reviewed paper (May 2023).  
*Engineered a protein-based “nano-computer” inside mammalian cells that processes two biochemical inputs with order-dependent outputs[5]. The device used a fusion of sensor proteins to detect a drug (rapamycin) and light; it produced different cellular responses (changing cell orientation to two distinct angles) depending on input sequence[5][6]. This noncommutative logic gate in live cells is a proof-of-concept for embedded decision-making in cell therapies, showing that cells can be programmed with multi-input logic (beyond simple AND/OR gates) to trigger specific behaviors. It also highlights progress in biocompatibility – the molecular circuit functioned in real time in a biological environment.*
- **DNA Computing for Data Search (Catalog Press Release 2022)** – Catalog Technologies Inc. – Vendor technical news (Dec 2022).  
*Catalog (a US startup) demonstrated a DNA-based computing platform that can search through DNA-stored data in parallel. Using their automated DNA writer “Shannon,” they encoded ~17,000 words of text into synthetic DNA in minutes and then performed a massively parallel search to retrieve all occurrences of a query word[9]. They scaled up to 200,000 words (eight entire books) and still found query matches with the same few chemical steps[10]. This shows unprecedented parallelism: search time was almost independent of database size, leveraging chemistry to do in one step what would require indexing in digital systems. Importantly, Catalog plans to scale to 100 million-word datasets and is developing a **rack-sized DNA computing platform** for enterprise use[10][15]. This indicates fast-paced progress toward practical deployment, with external partnerships and funding supporting a path to commercialization.\**
- **Microfluidic DNA Computing Chip (PLOS One 2023 / RIT News 2024)** – Amlan Ganguly et al. (RIT & Univ. of Minnesota) – Peer-reviewed + University report (Oct 2023, reported Jan 2024).  
*Developed a microfluidic integrated circuit for DNA computing that performs artificial neural network operations on DNA-encoded data[16]. This lab-on-chip device uses DNA strand concentrations to represent numbers and executes operations like addition and multiplication via DNA reactions[17]. The prototype ANN processor (implemented in a mini fluidic chip with embedded nanosensors) produced the correct outputs for simple neural-network computations, and it is being scaled up for visualization and testing[18][19]. This work marries molecular computing with hardware, aiming for standardized, reprogrammable DNA computing units. It demonstrates feasibility of compact, self-contained molecular computers and addresses integration and readout challenges by bridging biology with established chip fabrication techniques.*
- **Bitkom “Future Computing” Roadmap – DNA Computing Section (Germany 11/2023)** – C.F. Strnadl (Software AG) – Industry/consortium report (Nov 2023).

An authoritative tech outlook assessing DNA computing as experimental but advancing. It notes DNA/RNA computing can offer massive parallelism and high energy efficiency, but today it remains at TRL ~3–4 (lab proof-of-concept) and has not yet been validated outside controlled lab settings[20]. Key limitations are highlighted: molecular logic operations are slow, often requiring hours (vs. microseconds in silicon) due to chemical kinetics[21]; processes are labor-intensive and currently require automation to scale (manual pipetting and semi-automated equipment are still common)[22]; and costs are prohibitively high, needing  $\sim 10^6$ -fold reduction to become economical[23]. This report underscores that while scientific feasibility is proven, significant engineering breakthroughs (speed, error-correction, automation, cost) are needed for real-world deployment.

- **Digital DNA Classifier for Diagnostics (Advanced Materials 2025)** – Linghao Zhang et al. (BUCT, China) – Peer-reviewed paper (Mar 2025).  
 Demonstrated a multi-input molecular diagnostic classifier using a “Digital DNA Strand Displacement” (DDSD) scheme[24]. The DNA circuit could analyze multiple biomarkers and achieved 96% accuracy in distinguishing bacterial vs viral infections from clinical blood samples, and 100% accuracy in identifying specific pathogen types, surpassing prior molecular diagnostic methods[24][25]. The DDSD approach uses DNA polymerase-driven strand release to greatly reduce the number of DNA strands required, improving robustness. They also built cascaded DNA circuits handling up to 14 different signal levels (valences) with improved error suppression via DNA nanostructures[26]. This is a real-world-oriented validation – showing that molecular computing can interface with messy biological samples and provide medically relevant decisions. It represents a major step toward practical molecular computing applications (rapid infection diagnostics), albeit as a lab prototype.
- **Molecular-Motor Biocomputer Scaling (ACS Nano Au 2022)** – Pradheebha Surendiran et al. (EU Bio4Comp consortium) – Peer-reviewed paper (Oct 2022).  
 Achieved a  $128\times$  scale-up in network-based biocomputation, an approach where protein filaments (e.g. microtubules) explore nanofabricated channel networks to solve combinatorial problems in parallel[11][12]. They solved multiple instances of the NP-complete Exact Cover problem using a chip-sized network of channels and thousands of molecular motors running simultaneously. This work (part of an EU project) shows that an alternative molecular computing paradigm can tackle significantly larger problems than before, using highly energy-efficient parallel exploration. It indicates progress in fabrication and error control (the nanoscale rail networks were engineered to reliably guide molecules). While still experimental, it suggests that biological nano-machines can be harnessed for computing tasks that are hard for traditional computers, validating another branch of molecular computing beyond DNA chemistry.
- **Fast, Rewritable DNA Computing via Origami Registers (ACS Central Science 2024)** – Qian Zhang, Chunhai Fan et al. (Shanghai Jiao Tong Univ.) – Peer-reviewed paper, summarized by ACS (Dec 2024).  
 Reported a new “liquid computing” architecture with DNA origami registers that dramatically speeds up sequential DNA logic operations. By attaching a DNA-based logic register to a solid surface (a glass chip) and using it to hold and release intermediate DNA strands, the team eliminated manual transfer between reaction steps. They demonstrated that all steps of a multi-step DNA computation could occur in one pot within  $\sim 90$  minutes, versus many hours previously[8][7]. The register is reusable/resettable, enabling write–read–erase cycles similar to electronic memory[7][27]. They also integrated a signal amplifier to overcome diffusion limits, ensuring components find each other quickly. This result is a breakthrough in speed and automation: it lays groundwork for scalable, automated DNA circuit execution and real-time

operation, addressing two major bottlenecks (slow kinetics and tedious workflows) in molecular computing.

- **AI-Assisted Design of Genetic Circuits (Nature 2026)** – Caleb Bashor et al. (Rice Univ.) – Peer-reviewed paper, reported by Rice News (Jan 2026). Demonstrated the first use of machine learning to automate molecular circuit design. The team developed a platform (“CLASSIC”) that can generate and test hundreds of thousands of DNA circuit variants in human cells in parallel, creating massive datasets for training AI models[13]. With this, they showed that an ML model can learn the complex rules of genetic circuits and accurately predict new circuit designs that achieve desired outputs (tested in living human cell cultures)[14][28]. This greatly accelerates the design-build cycle: instead of hand-crafting circuits, researchers can leverage AI to navigate the huge design space. The study reported that ML-designed circuits performed better and more reliably than those designed by trial-and-error or simple models[28]. This is a strong indicator of maturity in the engineering tools ecosystem around molecular computing – moving toward data-driven, standardized design processes needed for scaling up complexity.

### 3. Maturity score (1–7) and reasoning

#### Overall Maturity Score: 3 (Laboratory Prototype demonstrated)

**A) Justification:** Molecular computing as a whole is **beyond mere theory (levels 1–2)** – multiple experiments over the last few years show real, working prototypes of molecular logic circuits and even complex functionalities like classification and learning in chemical systems. For example, **multi-layer DNA logic and neural network behavior have been achieved in vitro**[1][3], and molecular circuits have been embedded in living cells to control behaviors[5]. These successes indicate that fundamental feasibility issues (can molecules compute?) have been resolved, satisfying and surpassing level 2. We are squarely in the **laboratory prototype stage**: distinct prototypes tackle specific tasks (e.g. DNA data search[9], disease diagnostics[24], in-cell logic gates[5]), and crucial previously-blocking problems have been addressed one by one. For instance, the slow, sequential processing of DNA circuits has been accelerated by new designs (90-minute one-pot computation instead of multi-hour manual steps)[8][7], and error-prone complex circuits have been stabilized by novel architectures (DDSD, origami registers)[24][7]. These meet the rubric for level 3: **necessary functionality has been achieved in prototypes**, and key hurdles (multi-step cascades, scaling of parallelism, basic interfacing to real signals) have been proven solvable in principle.

However, **the technology is not yet at level 4 (validated PoC for commercialization)**. The current prototypes, while impressive, **do not fully meet practical deployment requirements** for broad use. Evidence for this gap includes:

- **Operating conditions & reliability:** Molecular computers still require controlled lab environments (temperature, cleanliness, specialized reagents). No evidence yet shows a **field-ready device** robust to outside conditions – e.g., the Bitkom report explicitly states DNA computing has *not been validated in any relevant real-world environment*[20].
- **Speed and throughput:** While speed has improved, it’s still orders of magnitude slower than electronics for general tasks. Even the “high-speed” DNA chip executes logic in minutes[7], whereas digital circuits do it in nanoseconds. The **intrinsic reaction rates (mass-action kinetics)** impose a ceiling that keeps many applications out of reach[21]. There is no evidence

yet of a molecular computer matching or exceeding conventional computing speeds except in very niche massively parallel searches[9][10].

- **Automation and integration:** Prototypes often involve manual steps or bespoke setups. Efforts like one-pot processing and surface-bound circuits are addressing this, but **true automation (like a push-button molecular CPU)** is nascent. The need for automation is emphasized as an unsolved challenge[22], and while startups like Catalog are building integrated machines, those are essentially advanced lab instruments at this stage, not widely-deployable products.
- **Cost and scalability:** All evidence points to **high costs and low throughput** currently. The Bitkom roadmap estimates DNA computing needs a million-fold cost reduction to be competitive[23]. Even though Catalog's approach scales well computationally, it still involves significant DNA synthesis and sequencing overhead. No **commodity manufacturing process** exists yet for molecular computing hardware – current implementations rely on expensive custom syntheses, enzymes, or nanofabrication. This means they are far from meeting cost or volume requirements of a commercial product (level 4 expects a viable path to production, which we don't yet see).
- **Actors and competition:** We do see the **beginnings of well-capitalized efforts** (e.g. Catalog's \$35M funding, Microsoft and academic partnerships, EU consortia). But the landscape is still limited – only a few specialized startups and labs are in the race, not (yet) a broad industry with multiple competing vendors. This suggests we have not reached level 5 where “several market actors” are pushing products. The field is still largely R&D-driven, with collaboration between academia and niche firms, indicating level 3–4 rather than 5+.

**B) Sub-score considerations:** The ART encompasses a **bundle of sub-technologies**, all under the umbrella of molecular computing:

- *DNA/RNA strand displacement computing (in vitro):* Maturity  $\approx$  **3.5**. Academically advanced with complex demos (neural nets[3], multi-layer logic[29]) and even early applied prototypes (diagnostics classifiers[24]). However, it remains lab-bound; no commercial device yet. (Scoring mid-Level 3; approaching 4 in specific niches like DNA data search where a prototype system exists[10].)
- *In vivo/Synthetic biology circuits:* Maturity  $\approx$  **2–3**. Fundamental logic gates in cells have been shown (e.g. protein logic gate with two outputs[5], CRISPR-based regulators in other studies). These are promising for future cell therapies, but still **early experimental** – complexity is low (a few inputs) and not productized. (Edge of level 2 and 3: basic functionality is shown, but far from a deployable therapy yet.)
- *Microfluidic and hardware-integrated molecular computers:* Maturity  $\approx$  **3**. Recent breakthroughs (DNA computing chip, DNA origami register on chip) show that integration and automation is possible[16][7]. They have built **lab prototypes** of “molecular computing devices,” meeting the definition of proof-of-concept hardware. None are market-ready, but they prove that physical packaging of molecular logic is achievable after long being a concern.
- *Parallel DNA computing for big data (e.g. storage+compute):* Maturity  $\approx$  **3–4**. Here, **exceeded classical capabilities** in some aspect (parallel search on unstructured data[9]). A company (Catalog) is actively engineering a platform, and even engaging with pilot customers. This sub-thread is closest to commercial: by showing a useful function (search) and planning a **scaled prototype** for enterprises, it edges into level 4 territory. Yet, until a working product or service is actually delivered and proven viable, we keep it at high-3.

- *Network-based biocomputation (molecular motors)*: Maturity  $\approx$  **2–3**. Progress is significant scientifically (solved larger math problems than before<sup>[11]</sup>), but this approach is highly experimental and not as directly tied to a near-term product. It's a visionary alternative with unknown scalability to practical computing tasks. (Solidly level 2 for now, with a lab demo marking level 3 for the concept.)

Given these sub-scores, the **aggregate score  $\sim$ 3** is appropriate. We weighted the more mainstream DNA computing developments a bit higher than fringe approaches. The DNA/RNA-based chemical computing – which is the core of the ART description – is around level 3: robust lab demonstrations, clear use-case interest, but **not yet a validated product or widely adopted tool**. Meanwhile, no sub-component has clearly achieved level 4 across functionality, cost, and reliability requirements, though some are close in one dimension (e.g. functionality for Catalog's search, or reliability within a lab setting).

**C) What's needed for Level 4:** To reach the next level, we would expect to see a **functional prototype system that convincingly works outside the research lab** – for example, a molecular computing device applied in a real operational setting (hospital, environmental field sensor, industrial bioreactor control) demonstrating practical value. This would require **improving speed and stability**, integrating error-correction so the device can run for long durations, and a form factor suitable for deployment. Cost and throughput would need to improve such that using the molecular approach is competitive for at least one application domain (perhaps DNA data search in an archival data center, or cell-based biosensors that operate autonomously). We would also expect by level 4 that **investors and industry show stronger commitment**, possibly a startup delivering a beta product or a government program running field trials. Those indicators have not fully materialized yet – current evidence shows continued research advancements but also acknowledges the significant gaps to commercialization<sup>[23][22]</sup>. Thus, the score remains at **3 – a proven concept with working prototypes, still awaiting the transition to practical, real-world validated technology**.

## Group 3 – Artificial Intelligence & Learning Systems

### ART 03.015 Causal Learning & Reasoning

#### 1. ART extraction

- **A) Primary capability (what the ART claims)**
- Build **explicit, machine-usable causal models** (cause–effect, intervention structure) rather than purely correlational predictors.
- Answer **intervention and counterfactual queries** (“what if,” “why,” “what caused this,” “what happens if we change X?”) with traceable causal pathways and uncertainty.
- Operate as **deployable software components** (libraries/frameworks/services) that integrate data + assumptions/domain knowledge and plug into larger decision-support/AI reasoning stacks.
- **B) Key sub-components / variants (bundle sub-threads)**
- **Causal effect estimation** (ATE/CATE, uplift, policy impact) from experiments and observational data (with assumptions).

- **Causal discovery / structure learning** (learning graphs/DAGs/MAGs; handling latent confounders; time-series and dynamical systems).
- **Causal representation learning** (recovering latent causal variables from high-dimensional observations; identifiability with interventions).
- **Causal generative modeling** (SCM-grounded generative models enabling controllable counterfactual generation).
- **Operational causal diagnosis / root-cause analysis** in complex systems (e.g., monitoring/logs, AIOps-like settings; human-in-the-loop refinement).
- **Benchmarking and evaluation infrastructure** (shared datasets, reproducible evaluation, standard metrics and protocols).
- **LLM-assisted causal reasoning** (LLMs proposing causal graphs/arguments, assisting setup, or learning causal structure/inference under controlled conditions).
- **C) Maturity indicators (what would count as evidence)**
  - **Working software artifacts** where users can specify causal assumptions/graphs, fit mechanisms, and answer causal queries with documented APIs and reproducibility.
  - **Competitive performance on benchmarks** with known ground truth (graphs/interventions), including **time-series and dynamical** settings and realistic confounding/noise regimes.
  - **Scalability evidence** (runtime/complexity results, distributed implementations, large variable counts, large sample sizes).
  - **Applied/production evidence**: deployed workflows in real organizations (e.g., large-scale observational studies, RCA/diagnosis pipelines), or systems evaluated on real operational data with measurable gains.
  - **Cross-actor ecosystem**: multiple well-capitalized actors + open-source communities pushing interoperable tooling, benchmarks, and methods (a sign of accelerating maturity).
  - **Known gaps** explicitly documented: robustness to hidden confounding, causal misspecification, dataset shift, and limits of purely observational discovery.

## 2. Evidence (10–20 recent, reliable sources)

### 1) DoWhy-GCM: An Extension of DoWhy for Causal Inference in Graphical Causal Models

- Authors/org: Patrick Blöbaum[1] et al.; Amazon Web Services[2]

- Venue/type: *Journal of Machine Learning Research (JMLR)* (peer-reviewed; open-source software track/MLOSS-style paper)

- Publication date: **May 2024** (Published 5/24)

- Link: <https://www.jmlr.org/papers/volume25/22-1258/22-1258.pdf>

- Why it matters: Demonstrates a **usable causal modeling library** that goes beyond effect estimation to queries like **root-cause attribution, distribution shift attribution, and causal structure diagnosis**, aligning directly with the ART’s “why/what-if” tooling vision. [3]

### 2) CausalBench: A Flexible Benchmark Framework for Causal Analysis and Machine Learning

- Authors/org: Ahmet Kapkic[4] et al.

- Venue/type: *ACM CIKM 2024* (peer-reviewed conference paper; benchmarking infrastructure)

- Publication date: **October 2024** (CIKM '24, Oct 21–25, 2024)
- Link: <https://arxiv.org/html/2409.08419v1>
- Why it matters: Provides an **evaluation platform** (datasets/models/metrics + reproducibility/versioning concepts) targeting the ecosystem need for **standardized causal ML benchmarking**, a key maturity accelerator for moving from research to dependable engineering practice. [5]

### 3) **Balancing Approach for Causal Inference at Scale**

- Authors/org: Sicheng Lin[6] et al.; includes deployment context at Snap Inc.[7]
- Venue/type: *ACM SIGKDD (KDD '23)* (peer-reviewed conference paper; large-scale causal inference systems)
- Publication date: **August 2023** (KDD '23, Aug 6–10, 2023)
- Link: <https://arxiv.org/pdf/2302.05549>
- Why it matters: Shows **scalable causal effect estimation** engineering (including runtime scaling to large datasets; single-node timing up to 1M rows and distributed runs on 10M-scale) and explicitly describes **productionizing** a workflow for observational impact estimation—strong maturity evidence for the “causal decision-support in practice” slice of the ART. [8]

### 4) **Deep Learning-Based Causal Inference for Large-Scale Combinatorial Experiments: Theory and Empirical Evidence**

- Authors/org: Zikun Ye[9] et al.
- Venue/type: *Management Science* (peer-reviewed journal; “Articles in Advance”)
- Publication date: **October 2025** (Published online 15 Oct 2025)
- Link: <https://rphilipzhang.github.io/rphilipzhang/DeDL-nonblind.pdf>
- Why it matters: Provides peer-reviewed evidence that causal/experimental inference problems in modern platforms can be treated in **large-scale, high-dimensional “combinatorial experiment” regimes** with deep-learning-based estimators—supporting plausibility and indicating advanced applied maturity in experimentation-heavy domains. [10]

### 5) **Disentangled Causal Graph Learning for Online Unsupervised Root Cause Analysis (CORAL)**

- Authors/org: Dongjie Wang[11] et al.
- Venue/type: Preprint (*arXiv*) with strong experimental detail (online RCA via causal graphs)
- Publication date: **May 2023** (Submitted 18 May 2023; later revisions noted)
- Link: <https://arxiv.org/abs/2305.10638>
- Why it matters: Presents an **online** causal-graph-based RCA framework with (i) near-real-time trigger detection, (ii) incremental causal graph updates, and (iii) root-cause localization, evaluated on **three real-world datasets**—evidence that causal reasoning components can operate as continuously-updated decision aids, not just offline analysis. [12]

### 6) **From Logs to Causal Inference: Diagnosing Large Systems (LOGos prototype)**

- Authors/org: Markos Markakis[13] et al.
- Venue/type: *Proceedings of the VLDB Endowment (PVLDB)* (peer-reviewed systems/data management paper)
- Publication date: **2024** (PVLDB 18(2):158–172, 2024)
- Link: <https://www.vldb.org/pvldb/vol18/p158-markakis.pdf>
- Why it matters: Demonstrates a **human-in-the-loop causal inference workflow over messy production logs**, including measured gains (e.g., ranker precision improvements over

baselines and reduced causal judgments) and a data prep pipeline with scaling behavior—concrete progress toward “embedded causal diagnosis” in operations settings. [14]

#### 7) **Causal Modelling: Tools for the high-tech industry**

- Authors/org: Emile van Gerwen[15] (with Johan Lukkien); TNO[16]
- Venue/type: Authoritative applied research report (not peer-reviewed journal, but a national applied research organization report)
- Publication date: **May 2025** (26 May 2025)
- Link: <https://publications.tno.nl/publication/34644344/Ajrn12zb/TNO-2025-P11200.pdf>
- Why it matters: Provides a **practitioner-oriented synthesis** of causal modeling for industrial decision support (including terminology, modeling choices, and tool discussions), reflecting institutional-level effort to translate causal methods into engineering practice—useful maturity evidence for real-world adoption pathways. [17]

#### 8) **Deep learning of causal structures in high dimensions under data limitations**

- Authors/org: Kai Lagemann[18] et al.
- Venue/type: *Nature Machine Intelligence* (peer-reviewed journal article)
- Publication date: **October 2023** (Published 26 Oct 2023)
- Link: <https://www.nature.com/articles/s42256-023-00744-z>
- Why it matters: Supplies high-quality evidence that causal structure learning can be combined with deep learning and prior knowledge to identify causal relationships across **thousands of variables**, supporting feasibility claims for some “large-scale causal world model” components (at least for specific domains and assumptions). [19]

#### 9) **Scalable Differentiable Causal Discovery in the Presence of Latent Confounders with Skeleton Posterior (Extended Version) (SPOT)**

- Authors/org: Pingchuan Ma[20] et al.
- Venue/type: Preprint (*arXiv*) aligned with KDD-style scalable causal discovery; focuses on MAG learning under latent confounding
- Publication date: **June 2024** (Submitted 15 Jun 2024)
- Link: <https://arxiv.org/abs/2406.10537>
- Why it matters: Addresses a core maturity blocker—**latent confounding** and scaling beyond small variable counts—explicitly stating prior limits (e.g., difficulty scaling MAG learning beyond ~50 variables) and proposing a framework intended to improve scalability and accuracy via skeleton posterior guidance. [21]

#### 10) **causalAssembly: Generating Realistic Production Data for Benchmarking Causal Discovery**

- Authors/org: Konstantin Göbler[22] et al.
- Venue/type: PMLR proceedings paper (peer-reviewed; UAI 2024 proceedings volume context)
- Publication date: **2024**
- Link: <https://proceedings.mlr.press/v236/gobler24a/gobler24a.pdf>
- Why it matters: Uses a real manufacturing assembly-line dataset plus domain knowledge to generate semisynthetic data **Markov w.r.t. a ground-truth graph** and benchmark multiple causal discovery methods—directly supporting maturity indicators around **realistic evaluation** and industrial relevance. [23]

### 11) **CausalTime: Realistically Generated Time-series for Benchmarking of Causal Discovery**

- Authors/org: Yuxiao Cheng[24] et al.
- Venue/type: *ICLR 2024* (peer-reviewed conference; OpenReview record)
- Publication date: **January 2024** (OpenReview published 16 Jan 2024)
- Link: <https://openreview.net/forum?id=iad1yyyGme>
- Why it matters: Tackles a practical maturity barrier—lack of ground-truth causal graphs for real time series—by generating **realistic time series with “ground truth” graphs** for benchmarking, enabling faster iteration toward deployable time-series causal discovery methods. [25]

### 12) **CausalDynamics: A large-scale benchmark for structural discovery of dynamical causal models**

- Authors/org: Benjamin Herdeanu[26] et al.
- Venue/type: *NeurIPS 2025 Datasets & Benchmarks Track* (peer-reviewed track artifact via OpenReview)
- Publication date: **September 2025** (Published 18 Sept 2025)
- Link: <https://openreview.net/forum?id=ck7euvU7V3>
- Why it matters: Provides a large-scale benchmark for dynamical causal discovery, including many graphs derived from coupled differential equations and climate models, evaluating robustness to **noise/confounding/lagged dynamics**—critical for moving “causal world models” beyond toy settings. [27]

### 13) **Interventional Causal Representation Learning**

- Authors/org: Kartik Ahuja[28] et al.
- Venue/type: *ICML 2023* (peer-reviewed conference; PMLR proceedings)
- Publication date: **July 2023** (23–29 Jul 2023)
- Link: <https://proceedings.mlr.press/v202/ahuja23a.html>
- Why it matters: Establishes identifiability results showing that **interventional data can enable recovery of latent causal factors** under fairly general settings, supporting the plausibility of learning causal representations that underpin counterfactual simulation modules. [29]

### 14) **Learning Linear Causal Representations from Interventions under General Nonlinear Mixing**

- Authors/org: Simon Buchholz[30] et al.
- Venue/type: *NeurIPS 2023* (peer-reviewed conference paper)
- Publication date: **December 2023**
- Link: [https://proceedings.neurips.cc/paper\\_files/paper/2023/file/8e5de4cb639ef718f44060dc257cb04f-Paper-Conference.pdf](https://proceedings.neurips.cc/paper_files/paper/2023/file/8e5de4cb639ef718f44060dc257cb04f-Paper-Conference.pdf)
- Why it matters: Pushes the theory/practice boundary on causal representation learning by providing **identifiability guarantees** under unknown interventions and nonlinear mixing, directly supporting the ART’s claim that hybrid learning can infer underlying mechanisms—not just correlations. [31]

### 15) **From Identifiable Causal Representations to Controllable Counterfactual Generation: A Survey on Causal Generative Modeling**

- Authors/org: Aneesh Komanduri[32] et al.

- Venue/type: Survey with journal reference (*Transactions on Machine Learning Research (TMLR)*; label: survey / review)
- Publication date: **May 2024** (arXiv revised May 23 2024; journal reference 2024)
- Link: <https://arxiv.org/abs/2310.11011>
- Why it matters: Systematizes methods that combine SCM concepts with deep generative models for **counterfactual generation and causal representation learning**, clarifying what is feasible today and what remains open—useful for plausibility assessment and maturity gap identification. [33]

#### 16) **Causal Reasoning and Large Language Models: Opening a New Frontier for Causality**

- Authors/org: Emre Kıcıman[34] et al.; Microsoft Research[35]
- Venue/type: *Transactions on Machine Learning Research (TMLR)* (peer-reviewed; OpenReview record)
- Publication date: **August 2024** (Published 14 Aug 2024; later certified for ICLR 2025 journal track)
- Link: <https://openreview.net/forum?id=mqoxLkX210>
- Why it matters: Provides benchmarked evidence that LLM-based methods can produce correct causal arguments and perform strongly on select causal tasks (pairwise causal discovery, counterfactual reasoning, event causality) while also documenting failure modes—directly relevant to the ART’s “LLMs calling causal solvers / helping causal setup” pathway. [36]

#### 17) **Causal Discovery and Inference through Next-Token Prediction**

- Authors/org: Eivinas Butkus[37] and Nikolaus Kriegeskorte
- Venue/type: *NeurIPS 2025* (peer-reviewed conference venue listing via OpenReview; research paper)
- Publication date: **September 2025** (Published 18 Sept 2025)
- Link: <https://openreview.net/forum?id=MMYTA3v66p>
- Why it matters: Claims (with experiments and mechanistic probes) that a GPT-style transformer can **discover linear-Gaussian SCM instances** and **answer counterfactual queries**, supporting plausibility of integrating foundation models with causal inference capabilities—while still limited to controlled SCM regimes. [38]

#### 18) **CounterBench: A Benchmark for Counterfactuals Reasoning in Large Language Models**

- Authors/org: Yuefei Chen[39] et al.
- Venue/type: Preprint (*arXiv*; benchmark dataset and evaluation)
- Publication date: **February 2025** (Submitted 16 Feb 2025)
- Link: <https://arxiv.org/abs/2502.11008>
- Why it matters: Introduces a 1K-question benchmark designed around **formal-rule counterfactual inference** and reports that many LLMs perform near random guessing; also proposes an iterative reasoning/backtracking method that improves results—strong evidence that “causal reasoning in LLMs” remains a maturity constraint and needs tool-like scaffolding. [40]

#### 19) **ExpliCa: Evaluating Explicit Causal Reasoning in Large Language Models**

- Authors/org: Martina Miliani[41] et al.
- Venue/type: *Findings of ACL 2025* (peer-reviewed proceedings track; dataset + evaluation)
- Publication date: **July 2025** (ACL 2025, July 27–Aug 1, 2025)

- Link: <https://aclanthology.org/2025.findings-acl.891.pdf>

- Why it matters: Adds a linguistically focused causal reasoning dataset (causal + temporal relations, different connective orders) and finds that even strong models struggle to reach high accuracy and often conflate temporal with causal relations—evidence that natural-language causal interfaces need robust causal backends, not just fluent text generation. [42]

### 3. Maturity score (1–7) and reasoning

- **A) Final maturity score: 4**
- **B) Justification mapped to the rubric**
- **What evidence rules out levels 1–3 (the “only theory / only lab demo” range):**
  - There are multiple **functionally usable software artifacts** and prototype systems that operationalize causal modeling and causal querying beyond basic effect estimation, e.g., DoWhy-GCM enabling diverse causal queries “with just a few lines of code.” [3]
  - There is strong evidence of **scaled, engineering-oriented causal inference** work aligned with real platform needs (distributed/large data, operational constraints), including an end-to-end observational study workflow described as productionized in a major company setting. [8]
  - There are peer-reviewed systems papers demonstrating causal inference in operational contexts (e.g., causal diagnosis from raw logs) with measurable performance/effort improvements and artifact availability—well beyond a purely conceptual stage. [14]  
Collectively, this places the ART above “lab principle” and “single prototype” maturity, because functional prototypes exist and are demonstrated on real or operationally-inspired data with measured outcomes.
- **Why this is not yet level 5 (and above) for the ART as a whole:**
  - The ART description implicitly targets **generalizable causal learning and reasoning services** spanning domains, including robust causal discovery under hidden confounding, dynamic world models, and trustworthy counterfactual answering integrated into broader reasoning systems. Evidence shows **active progress**, but also highlights that core components remain fragile or benchmark-constrained:
  - Causal discovery (especially with latent confounders and in dynamical/time-series regimes) is still heavily driven by research benchmarking and method development rather than broadly standardized, push-button production deployment. [43]
  - LLM-based causal reasoning remains inconsistent: formal counterfactual reasoning is often near random without specialized scaffolding, and explicit causal reasoning datasets show persistent errors and confusions. [44]
  - To justify level 5 for the ART *as a whole*, the missing evidence would include: broadly adopted **production-grade “causal reasoning modules”** (across multiple sectors) with clear scaling economics and standardized interfaces; robust validation playbooks for hidden confounding and causal misspecification; and repeated proof that causal discovery and counterfactual

modules maintain reliability under real-world drift and incomplete observability. The recent literature instead suggests tool proliferation + benchmarking, but not yet “production prototype finishing phase” across the full bundle. [45]

- **C) Sub-component maturity breakdown and aggregation**
- **Causal effect estimation & experimentation at scale → ~6**
  - Evidence: large-scale/industrial causal inference methods and workflows are described with distributed scaling and productionization; peer-reviewed journal work addresses large combinatorial experiments. [46]
- **Operational causal diagnosis / root-cause analysis systems → ~5**
  - Evidence: LOGos (PVLDB 2024) demonstrates a prototype causal workflow over real logs with measured improvements; DoWhy-GCM supports root-cause/distribution-shift causal queries as library features. [47]
- **Causal discovery at scale (latent confounders, time-series/dynamical) → ~4**
  - Evidence: SPOT directly targets scalability under latent confounding constraints; multiple benchmark frameworks (CausalTime, CausalDynamics) exist to stress-test methods in more realistic regimes, indicating PoC-quality infrastructure but not generalized deployment. [43]
- **Causal representation learning & causal generative modeling → ~3**
  - Evidence: peer-reviewed ICML/NeurIPS work provides identifiability results and implemented approaches under intervention assumptions, and surveys synthesize the field; however, these methods are not yet demonstrated as stable, general-purpose production components. [48]
- **LLM-assisted causal reasoning / causal setup assistance → ~3**
  - Evidence: TMLR work shows strong performance on several causal-argument tasks, but benchmark datasets indicate persistent failures in explicit and formal counterfactual reasoning; NeurIPS 2025 results show promise in controlled SCM settings. [49]
- **Aggregation to a single ART score:**
  - Because the ART’s benefits are split across multiple application areas and technical threads (scalable effect estimation vs. causal discovery vs. causal representation learning vs. LLM integration), an **average-based score** is most appropriate per the rubric guidance. Averaging the above rough sub-scores (6, 5, 4, 3, 3) yields approximately **4.2**, which conservatively maps to **ART maturity level 4** (“PoC exists and is functional, but broad production scaling and reliability across contexts is not yet demonstrated”). [50]

## ART 03.016 Federated & Privacy-Preserving Learning

### 96. ART extraction

**A. Primary capability:** Enables collaborative machine learning on sensitive, distributed datasets without pooling raw data centrally. Models are trained **at data sources** (e.g. user devices or different organizations) and only **privacy-safe updates** (not personal data) are shared, so useful patterns can be learned while preserving confidentiality. This allows AI to leverage fragmented data (that couldn't legally or safely be centralized) by "**bringing the code to the data**" instead of copying data into one place.

### B. Key sub-components/variants:

- **Federated learning algorithms:** Methods like Federated Averaging dispatch an initial model to participants, train locally, and aggregate updates on a server. Variants include **cross-device FL** (many low-powered devices like phones) vs **cross-silo FL** (fewer institutional nodes), as well as techniques like **split learning** and **swarm learning** (decentralized peer-to-peer training).
- **Secure aggregation protocols:** Cryptographic methods (secure multi-party computation, homomorphic encryption) that **encrypt or mask model updates** so that a server or eavesdropper cannot decipher any single participant's data. These ensure only aggregated results are available, preventing reverse-engineering of individual contributions.
- **Trusted execution environments (TEE):** Secure hardware enclaves (e.g. Intel SGX) that run the training code in an isolated, encrypted zone on each device or server. TEEs prevent even privileged insiders from inspecting the data or model updates during computation, adding a hardware layer of privacy assurance.
- **Differential privacy (DP):** Statistical noise injection techniques applied to model updates to **limit information leakage** about any individual data point. By adding carefully calibrated randomness, DP provides quantified privacy guarantees (e.g. an  $\epsilon$ -differential privacy budget) so that the global model or gradients do not reveal specifics of any one user's data.
- **Federation infrastructure & orchestration:** Systems for managing connectivity, scheduling, and aggregation across distributed nodes. This includes coordination servers, networking protocols, and federated learning frameworks (open-source platforms like TensorFlow Federated, PySyft, FATE, NVIDIA FLARE, etc.) that provide tools for deploying FL at scale. These handle heterogeneity in device capabilities, unreliable connections, and

orchestrate rounds of training and model fusion.

- **Privacy/utility balancing methods:** Specialized algorithms to tackle FL challenges such as non-IID data (imbalanced or silo-specific data distributions), communication efficiency (reducing bandwidth or rounds), and fairness. For example, personalization layers allow local tailoring of the global model, and adaptive optimization or data weighting can help when some nodes have scarce data. These ensure the federated approach remains effective even when data across partners is uneven or limited.

### C. Maturity indicators:

- **Peer-reviewed prototypes and field trials:** Evidence of federated learning working on real sensitive data (e.g. multi-hospital studies, cross-bank collaborations) with metrics close to conventional centralized training. For example, published case studies or challenge results where a federated model achieves accuracy comparable to a model trained on pooled data would indicate technical feasibility.

- **Production deployments and products:** Signs that major tech companies or industries have moved FL out of the lab. This could include **shipping features** (e.g. a smartphone app or IoT service that uses on-device federated updates), cloud services offering “federated learning” to clients, or open-source frameworks reaching version 1.0 and being adopted in industry. Multiple well-funded actors (Google, Apple, NVIDIA, Huawei, etc.) actively developing and offering FL solutions or incorporating privacy-preserving learning in their platforms would show competition and investment.

- **Scalability and performance benchmarks:** Reports that FL systems can handle large numbers of participants or large models with acceptable overhead. Maturity would be indicated by overcoming the initial performance penalties – e.g. algorithms or hardware that significantly reduce the extra communication, or protocols that handle millions of devices. Demonstrations of federated training on realistic scales (millions of users or very high-dimensional models) or integration of acceleration (efficient secure aggregation, use of GPUs in enclaves, etc.) suggest readiness for broad use.

- **Standards and consortium adoption:** Emergence of **standards, best practices, or regulatory endorsements**. For example, an IEEE or ISO standard for federated learning architecture, or guidelines from data protection authorities endorsing FL as a privacy measure. Industry consortia (in healthcare, finance, etc.) establishing FL networks, and references to FL in privacy regulations or government AI strategies would show the approach is recognized as a viable solution.

- **Commercial services and cost models:** If companies are offering federated learning as a service (with pricing), or if organizations budget for FL infrastructure as part of their AI deployments, it implies a mature value proposition. Evidence like cloud providers supporting FL APIs, startups selling FL-powered analytics, or surveys showing increased adoption in multiple sectors would indicate that federated, privacy-preserving learning is crossing into mainstream use.

#### 97. Evidence (10–20 recent, reliable sources)

98. **Federated Learning in Public Health: A Systematic Review of Decentralized, Equitable, and Secure Disease Prevention Approaches** — S. T. Shah et al., *Healthcare (MDPI)* – Oct 2025. This peer-reviewed review analyzed 19 studies (2020–2025) applying FL in public health settings. It found that **federated models across multiple institutions preserved privacy while improving generalizability** of disease detection models, enabling “near real-time intelligence” from diverse data that could not be centralized<sup>[1]</sup>. However, it notes ongoing

barriers like data heterogeneity, interoperability gaps, and unclear legal pathways, implying that **FL is promising for secure analytics but needs better standards and regulatory guidance** to reach routine use[2]. (Peer-reviewed paper)

99. **Fair evaluation of federated learning algorithms for automated breast density classification: Results of the 2022 ACR–NCI–NVIDIA FL challenge** — *K. Schmidt et al., Medical Image Analysis – July 2024*. In this international challenge, algorithms were trained on **simulated mammography data from 3 separate hospitals** without pooling patient images. The **winning federated model achieved performance (kappa ~0.65) comparable to a centrally-trained model**, demonstrating that FL can reach centralized accuracy in medical imaging[3][4]. Notably, the smallest data site hurt performance, highlighting the need for methods to handle imbalanced data. This result gives experimental proof that federated training can produce high-quality models in healthcare, validating the approach’s **plausibility and indicating progress toward practical viability**. (Peer-reviewed journal article)
100. **TechDispatch: Federated Learning** — *European Data Protection Supervisor (EDPS) – June 2025*. This EU regulatory bulletin discusses FL as a **privacy-preserving technology** aligned with data protection principles. It confirms that in FL, only model updates (gradients/weights) are shared while raw personal data stays local[5], reducing exposure and breach risk. However, the EDPS also warns of unresolved challenges: even model updates can leak sensitive information (through reverse engineering or **membership inference attacks**), so FL implementations must mitigate these risks[6]. The report’s balanced view — highlighting FL’s compliance benefits alongside its new threat vectors — underscores that the technique is **taken seriously by regulators** but must mature further (through robust privacy techniques and “data protection by design”) before being fully trusted. (Authoritative tech report by EU regulator)
101. **Federated learning frameworks: quality and interoperability for biomedical research** — *M. Chavero-Diez et al., NAR Genomics and Bioinformatics – Feb 2026*. This peer-reviewed article systematically reviewed current open-source FL frameworks (e.g. TensorFlow Federated, PySyft, FATE) for use in biomedical research. It found an **ecosystem of many FL platforms** with good availability and reusability, but **poor interoperability and sparse integration of advanced privacy tools**[7]. Most frameworks are designed for specific use-cases and mainly support basic horizontal FL; features like differential privacy or secure multi-party computation are often missing, and frameworks don’t easily work together. This suggests that while multiple actors have built FL infrastructure (a sign of interest and partial maturity), the **fragmentation and lack of built-in privacy enhancements may hinder scalability and wide adoption**. The paper calls for more flexible, privacy-aware framework design moving forward. (Peer-reviewed review, academia)
102. **Privacy-Preserving Federated Learning on AWS with NVIDIA FLARE** — *K. Kersten (NVIDIA) & U. Khalid et al. (AWS), AWS Partner Network Blog – Nov 2022*. This technical blog introduces **NVIDIA FLARE**, an open-source SDK for federated learning, and its deployment on AWS Cloud. FLARE evolved from NVIDIA’s Clara healthcare platform and **has already been used to build numerous AI applications in medical imaging**[8]. The post details FLARE’s architecture for secure collaboration, including components for provisioning federations and encrypted communication. Notably, **FLARE comes with built-in support for differential privacy and even homomorphic encryption filters** to protect data during training[9]. The availability of such a robust, enterprise-grade FL toolkit indicates a **commercial push toward scalable federated learning**. That AWS and NVIDIA jointly promote it shows industry validation, and its real-world use cases in healthcare illustrate growing maturity (moving from research to practical toolchains). (Vendor technical documentation / blog)

103. **Intel & Ping An: Break Down Data Silos with Hardware-enhanced Security (Case Study)** — *Intel & Ping An Technology (China) – Jan 2023*. This case study describes how Ping An (a major Chinese financial and healthcare tech company) integrated Intel’s SGX trusted execution environments into their federated learning platform. By running FL within SGX enclaves, Ping An **secured multi-source data collaboration across insurance, healthcare, voice, and IoV (telematics) applications**[10]. The document reports “*noteworthy results*” and positive user feedback in these domains, implying the approach is working in practice. A Ping An engineer is quoted emphasizing that **Intel SGX creates trusted hardware zones for each data source, ensuring privacy and boosting AI model training with multi-party data**[11]. This demonstrates a real-world deployment of federated learning enhanced by hardware security, indicating that at least some businesses have moved beyond prototypes to implementing FL for sensitive data analytics. (Vendor case study – cautious use as it’s a corporate publication, but concrete in reporting deployment and impact)
104. **Differentially private knowledge transfer for federated learning** — *T. Qi et al., Nature Communications – June 2023*. This peer-reviewed study addresses the performance penalty of strict privacy in FL. The authors propose “PrivateKT,” a method using a small public dataset to transfer knowledge, achieving markedly better utility under strong privacy. **In experiments, PrivateKT closed ~84% of the accuracy gap between a centrally-trained model and a federated model with rigorous differential privacy ( $\epsilon$  as low as 1)**[12]. This is significant evidence that the **technical feasibility of privacy-preserving learning is improving** – the accuracy trade-offs can be mitigated. It supports the plausibility of the ART by showing that even under legal-grade privacy constraints (DP), models can approach conventional performance. Such advances in algorithms are crucial for federated learning to become standard; they indicate the research community is actively solving remaining barriers (like privacy vs. accuracy). (Peer-reviewed research paper)
105. **Efficient Differentially Private Secure Aggregation for Federated Learning (USENIX Security ’22)** — *T. Stevens et al., 31st USENIX Security Symposium – Aug 2022*. This academic work (peer-reviewed) presents a new cryptographic protocol that combines secure aggregation with differential privacy, without needing a trusted third party. It leverages hardness of lattice problems (Learning with Errors) to protect gradients. The authors report that their protocol **outperforms prior art and scales to large numbers of clients while maintaining optimal model accuracy under DP**[13]. This evidence shows progress on the scalability and efficiency front: federated learning can be made **both secure and performant at scale** via advanced cryptography. It indicates that previously blocking issues (e.g. high overhead of secure aggregation, or too much noise from DP) are being addressed, a sign that the technology bundle is steadily moving from theoretical possibility toward practical deployment in larger networks. (Peer-reviewed conference paper)
106. **WeBank FATE Case Study – Accelerating Secure Computing for Federated Learning** — *WeBank AI & Intel, case study (PDF) – Nov 2022*. This joint report highlights outcomes from deployments of **FATE (Federated AI Technology Enabler)**, an open-source FL platform originally from China’s WeBank. Two real-world impacts are quantified: (a) In a healthcare scenario, **small hospitals using horizontal FL saw 10–20% higher diagnostic accuracy** for stroke prediction compared to using only their own data, while keeping patient data local[14]. A modeling of scale-up suggests that if 10% of China’s population were covered by such federated early-disease prediction, it could save ~¥200 million annually in healthcare costs[15]. (b) In finance, a federated credit scoring solution using data from multiple institutions improved the risk model’s effectiveness by **12%** and cut credit approval costs ~5–10%, all with privacy protections in place[16]. These concrete metrics from large-scale trials show that federated learning is not only feasible but **adds value in production settings**,

reducing key bottlenecks (data sharing barriers) and delivering economic benefits. The fact that WeBank's FL platform is **adopted by various organizations** and now part of Linux Foundation's ecosystem further underlines the growing maturity and industry uptake. (Vendor/consortium technical report)

107. **Advances in private training for production on-device language models (Gboard)** — Z. Xu & Y. Zhang, *Google Research Blog* – Feb 2024. Google details how its Gboard keyboard app now trains its predictive text models via federated learning with rigorous privacy. By 2024, **over 30 on-device language models across 7+ languages and 15+ countries are being trained with federated learning combined with formal differential privacy guarantees**[17]. The DP protection is strong ( $\delta=1e-10$  and  $\epsilon$  often  $<1-10$  range), making this the **largest production deployment of user-level DP + FL** to date[18]. They also mention techniques like secure aggregation (encryption of updates) and client-side data controls in use[19]. This source is compelling evidence of maturity: a tech giant has integrated the full federated, privacy-preserving stack (FL + DP + SecAgg) into a live product used by millions. It shows that the ART's approach is not only plausible but already **delivering value at scale (lower latency and privacy by design for users)**, and that the engineering hurdles (communication at scale, privacy accounting) have been overcome in at least one major domain (mobile AI). (Industry blog post, describing a deployed system with technical detail)
108. **Swarm learning for decentralized AI in cancer histopathology** — O. L. Saldanha et al., *Nature Medicine* – Apr 2022. This study demonstrated a variant of federated learning ("swarm learning" using a blockchain-based peer-to-peer approach) on a large medical dataset. **Five thousand patient pathology images from Northern Ireland, Germany, and the USA were used to train an AI model collaboratively without data sharing**[20]. The swarm-trained model predicted cancer genetic markers as accurately as a model trained on centrally merged data, and better than models trained in isolation at each hospital. This shows that even in highly regulated, multi-national settings, distributed learning can produce **high-quality models while avoiding legal barriers of data pooling**. The success across continents and the fact that performance kept up with conventional training underscore the **scientific feasibility and potential impact** of privacy-preserving learning in critical domains like cancer diagnosis. (Peer-reviewed article)

#### 109. **Maturity score (1–7) and reasoning**

##### **A. Final Maturity Score: 6** (Products delivered and scaling)

**B. Justification:** Federated and privacy-preserving learning has **progressed beyond lab prototypes (Levels 2–3)** and even beyond isolated proof-of-concepts. We see **functional production deployments** – for example, Google's Gboard shipping to millions of users with federated, differentially private training in place[18]. Such deployments prove that the key technical barriers (distributed optimization, basic privacy protection) have been solved to a degree that meets real-world requirements, ruling out lower maturity levels. Multiple well-funded actors are actively developing and adopting FL (Google, NVIDIA, Intel, WeBank, Apple, healthcare consortia), indicating **competition and investment consistent with Level 5**. The evidence of actual **products and services being delivered** pushes the score to **Level 6**: Gboard's ongoing global rollout, NVIDIA's FLARE platform being used in practice, and Ping An's industry applications show that federated learning is being implemented for end-users or clients today (often internally financed as part of bigger products). Furthermore, application areas are expanding (mobile keyboards, healthcare diagnostics, finance, IoT), and efforts are underway to reduce costs/overheads – e.g. new protocols to cut bandwidth or use hardware to secure data[10][13]. These are signs of scaling and maturing ecosystems.

**Why not Level 7?** The technology hasn't yet reached ubiquitous adoption or a state of **wide market competition in off-the-shelf FL products**. While there are multiple frameworks, we don't yet see many standalone federated learning products with a broad customer base and **independent demand**. Many deployments are either internal (Google, Apple using it for their own apps) or pilot collaborations in specialized fields (medicine, finance). Some critical challenges remain before full commoditization: e.g. seamless interoperability between frameworks[7], stronger guarantees against information leakage[6], and ease-of-use for organizations without deep ML expertise. In short, the field is at the stage of **early products and expanding pilots (6)**, but not yet a default component in every AI deployment (which would merit 7 when "competing products and rising demand" are clearly observable). Evidence like the EDPS report and framework reviews show that **integration and standardization are still in progress**, and not all privacy-preserving techniques are production-ready (for example, fully homomorphic encryption in FL is still experimental). Thus, it hasn't fully crossed into the "competitive growth" phase despite clear momentum.

**C. Sub-component breakdown:** The ART comprises a bundle of technologies that are maturing at slightly different paces, but they converge to enable the same overall functionality (privacy-preserving collaborative learning):

- *Core federated learning algorithms:* **Level 6**. The concept of training on distributed data is well-demonstrated and in use (e.g. federated optimization algorithms like FedAvg running on **millions of phones in production**[18]). Multiple tech companies and open-source projects have production-grade implementations, indicating a mature core.
- *Differential privacy in federated ML:* **Level 5–6**. Research of the last few years (e.g. DP-FTRL and PrivateKT) and Google's deployment show that formal DP can be applied at scale with acceptable performance[18][12]. At least one major deployment (Gboard) uses it, but outside of big tech, many FL applications still do not implement strong DP, suggesting uneven adoption (hence on the cusp of 6).
- *Secure aggregation & cryptographic protocols:* **Level 5**. Secure aggregation (basic encrypted averaging of updates) is already employed in practice (Google's system, for instance) and frameworks like NVIDIA FLARE include it[9]. Advanced cryptographic FL (MPC, homomorphic encryption) is more nascent – demonstrated in academia and some pilot projects, but not widely deployed due to complexity. This sub-tech is closer to Level 3–4 in isolation (lab demonstrations like the USENIX '22 protocol[13]), but simpler versions are in production use (hence averaging to ~5).
- *Trusted hardware enclaves:* **Level 4–5**. The use of TEEs for FL security has been proven (Ping An's implementation with Intel SGX[10]) and a few platforms support it, but it's not yet common across deployments. It's moving from prototype to early adoption in sensitive industries.
- *Ecosystem and standards:* **Level 5**. The field has multiple frameworks and consortium-driven platforms (indicating competition and interest), and regulators acknowledge FL as a promising PET (privacy-enhancing tech)[21]. Efforts like FATE (Linux Foundation) and IEEE standards show coordination, but full interoperability and plug-and-play ease aren't there yet[7].

Given these subcomponents serve one integrated purpose and the **highest-impact implementations (federated + DP)** are already at a high maturity, we assign the overall ART the score **6**. We weight the score toward the most developed aspects (since an organization can achieve the ART's goal today by using the mature pieces, even if not all approaches are

equally advanced). In summary, federated and privacy-preserving learning is **commercially deployed and scaling in certain domains (supporting Level 6)**, though some supporting techniques are still catching up, and broader adoption should follow as those gaps close.

## ART 03.017 Trustworthy AI Systems

### 110. ART extraction

111. **Primary capability:** Enabling AI systems to operate **reliably and safely without constant human supervision** in high-stakes domains. This means AI that is *predictable, auditable, and aligned with explicit rules/values* even under stress, errors, or attacks. It would *reduce the need for human oversight* by providing understandable outputs (with explanations, confidence metrics) and automatic fail-safes.

### 112. Key components & variants:

- **Robust & Resilient AI algorithms:** Machine learning models (e.g. deep networks) trained or structured to *withstand adversarial inputs, distribution shifts, errors, and perturbations* without unpredictable failures. This includes adversarial training, certified robustness techniques, and redundancies for safety.
- **Formal verification & validation:** Methods to *formally prove or verify* certain properties of AI components (e.g. proving a neural network controller will not violate safety constraints within defined conditions). Also rigorous testing, simulation, and validation protocols to guarantee performance *within a specified operating envelope*.
- **Secure execution environments:** Deployment setups that use *trusted hardware or cryptographic techniques* to ensure the AI model and data cannot be tampered with or leaked. This ranges from trusted execution environments (enclaves) for AI inference to federated or privacy-preserving learning that maintain data confidentiality.
- **Monitoring and self-monitoring layers:** Integrated *sensing of the AI's own behavior and context* – e.g. runtime monitors for anomalies, bias detection, concept drift or performance degradation. The AI can flag when it is operating out of its trained domain or when uncertainties are high.
- **Explanations and transparency tools:** Mechanisms for the AI to provide *human-interpretable explanations, decision rationale, provenance of data used, and calibrated confidence scores* for its outputs. This helps users and auditors understand *why* the AI made a decision and whether to trust it.
- **Objective and constraint interfaces:** Clear interfaces for humans to *configure the AI's goals, rules, and escalation policies*. For instance, setting ethical constraints or fairness criteria that the AI must follow, and defining when the AI should hand control back to a human or go into a safe fallback mode.

- **Self-correction and fail-safe mechanisms:** The AI system can *automatically adjust or shut down* when it detects potential failures. For example, an autonomous vehicle's AI might revert to a safe-state or request human intervention if sensors malfunction or if an unrecognized scenario occurs.
  - **Lifecycle governance & traceability:** Tools and processes for *tracking training data provenance, model versions, and policy changes* over time. This includes audit logs, model “datasheets” or cards documenting performance and limitations, and pipelines that ensure updates to the AI are reviewed for compliance with safety and ethics guidelines.
113. **Maturity indicators:** Evidence would include **working prototypes and deployed systems** that embody these features. Key signs: (a) **Successful field trials or deployments** of AI in high-stakes settings (medicine, transportation, etc.) operating with minimal incidents under monitored conditions. (b) **Proof-of-concept demonstrations** of self-monitoring AI triggering safe fallbacks or handoffs in response to anomalies. (c) **Formal certification or verification results** for AI components (e.g. a neural network with mathematically proven safety bounds). (d) **Competition and investment** – multiple companies releasing “AI assurance” tools (for robustness, explainability, fairness) or integrating them into products, and industry standards/best-practice frameworks being published. (e) **Regulatory or enterprise adoption** – e.g. requirement of explainability or bias audits in procurement, showing these technologies are moving from lab to real-world requirement. (f) **Performance benchmarks** that show improvements: e.g. robust models that maintain high accuracy under attacks or across data shifts, or explainability tools that demonstrably improve user trust or debugging. (g) **Integration into ML platforms** – major AI providers offering built-in features for fairness, drift detection, secure model serving, etc., indicating commercial viability and scaling.
114. **Evidence (10–20 recent, reliable sources)**
115. **Adversarially Robust Models at Scale – Wang et al. (UCSC), CVPR 2024 (peer-reviewed) – June 2024. Finding:** Demonstrates a breakthrough in training large vision models with adversarial robustness. By adversarially training a Vision Transformer on a 1-billion-sample dataset, they achieved **71.0% robust accuracy on ImageNet ( $\ell_\infty$  norm attacks)** – a ~12% absolute improvement over prior state-of-the-art<sup>[1][2]</sup>. *Why it matters:* This shows that the *once “brittle” deep models can be made significantly more robust* to adversarial inputs when scaled and trained properly, indicating the scientific feasibility of robust AI required for trustworthy systems. It also proves out new techniques (like their AdvXL framework) to overcome previous scalability problems in robust training, a key step toward deployment in the wild.
116. **Microsoft Responsible AI Toolbox – Besmira Nushi et al., Microsoft Research blog (open-source toolkit) – Feb 2023. Finding:** Microsoft released an open-source Responsible AI Toolbox integrated with Azure ML, providing *interoperable tools for error analysis, fairness assessment, interpretability, and mitigation tracking*<sup>[3]</sup>. Notably, the toolbox includes a “Mitigations” library and a “Tracker” that lets users test bias mitigation techniques and *visualize model performance broken down by subgroups* to detect hidden failure modes<sup>[4]</sup>. *Why it matters:* It indicates *industry-grade tooling is now available to operationalize trustworthiness*. Practitioners can systematically debug models, enforce fairness metrics, and document improvements – suggesting that concerns like bias and explainability are being addressed at scale in real development pipelines (a sign of growing maturity beyond academic proofs-of-concept).

117. **Amazon SageMaker ML Lineage Tracking – Amazon Web Services documentation** (vendor technical doc) – Nov 2023. **Finding:** AWS’s production ML platform now offers automated *lineage tracking* for models: it records every step from data prep to training to deployment, tracking datasets, parameters, model artifacts, and versions[5][6]. This allows one to *reproduce models, audit their exact data sources, and prove compliance* with governance standards. *Why it matters:* High-stakes AI demands traceability. The existence of *built-in lineage and governance in a leading cloud ML service* shows that the industry recognizes the need for **accountability and auditability**. It’s evidence of *commercialization* of trustworthy AI practices – clients (like banks or healthcare) can meet regulatory requirements by using these tools, reducing the friction that previously blocked AI deployment due to lack of transparency.
118. **Autonomous Medical AI Deployment (IDx-DR) – Hunfeld et al., Scientific Reports (peer-reviewed)** – Jan 2026. **Finding:** A real-world clinical evaluation of an FDA-approved autonomous AI (IDx-DR for diabetic retinopathy) on 875 patients showed it could *safely handle a majority of cases*. The AI’s diagnostic system **successfully analyzed 63.4% of patient cases on its own**, flagging ~26% as “not analyzable” (poor image quality) for human follow-up[7]. For severe disease, its performance reached **94.4% sensitivity and 90.5% specificity** (versus expert ophthalmologists) when good-quality inputs were available[8]. *Why it matters:* This is *tangible proof of a trustworthy AI in practice*. The system had *built-in fail-safes* (it outputs “image insufficient” rather than risking a wrong diagnosis), and it provided high accuracy in detections – addressing safety and effectiveness in a high-stakes domain. It also shows that *regulators have begun approving such systems*, and they are being deployed to augment healthcare – a strong indicator that the technology (at least in constrained scopes) has passed proof-of-concept into real operation.
119. **NIST AI Risk Management Framework (RMF) – NIST report, National Institute of Standards and Technology** (U.S. Govt, standards roadmap) – Jan 2023. **Finding:** This authoritative framework defined **“trustworthy AI” characteristics** including validity, reliability, safety, *security/resilience*, explainability, privacy, and **fairness (bias management)**. For example, it specifies that *secure and resilient AI systems “withstand unexpected adverse events or changes...and degrade safely and gracefully when necessary.”*[9] Likewise, “Fair AI” is defined as having *harmful bias managed*, noting three sources of bias (systemic, statistical/computational, human) that must be addressed[10]. *Why it matters:* This shows a *broad consensus and clarity on what technical measures are needed* for trustworthiness. The RMF (while voluntary) is being adopted as a baseline – its detailed guidance (e.g. on testing for bias or ensuring fail-safe behavior) reflects that the field has matured to the point of *codifying best practices*. It also pushes developers toward measurable standards, accelerating development of tools for alignment, bias mitigation, and robust design (many of which we see emerging in other evidence here).
120. **Out-of-Distribution (OOD) Detection in AI – Mortier et al., Bioinformatics (peer-reviewed)** – 2025. **Finding:** Demonstrated that modern OOD detection methods can reliably *catch when new input data falls outside a model’s training distribution*. In testing on biomedical data, six different OOD algorithms were able to **accurately identify novel cell types** and *flag significant data shifts* in gene expression datasets[11]. *Why it matters:* An AI that monitors its own input for “unfamiliar” patterns is crucial for self-monitoring and safe deployment. This study provides experimental evidence that such mechanisms work: the AI *can detect when it might be entering an unknown regime* where its predictions could be invalid. It is a step toward the “*internal shift detection*” described in the ART: practically, systems like this could trigger an alert or fallback mode when conditions stray beyond what they were trained on – an essential component for trustworthy autonomy.

121. **Human Trust and Explanations Study – Nicolson et al., *npj Digital Medicine* (peer-reviewed) – Nov 2025. Finding:** In a clinician user study, adding explainable AI features had *mixed effects* on trust and performance. An explainable model for ultrasound imaging did *increase clinicians' confidence* in the AI, but **explanations had no significant effect on overall trust or reliance** on the AI's recommendations[12]. Some clinicians even performed worse with AI explanations than without. *Why it matters:* This is a reality-check that while explainability tools are available (and indeed being deployed), *they don't automatically solve the trust issue in practice*. Users may not uniformly benefit from them, highlighting a maturity gap: the technology for generating explanations exists (and is a pillar of trustworthy AI), but achieving *consistently improved human-AI trust and outcomes* may require further refinement of how explanations are presented or used. It underscores that *"trustworthy AI" is not just a checklist of features; it requires validation in human interactions*. The ongoing research here is evidence that we are in a formative stage of learning how best to integrate these tools for true value.
122. **Confidential Computing for AI – Elsie Jang, Confidential Computing Consortium Workshop report (technical blog) – Jan 2026. Finding:** Progress in secure AI execution is marked by hardware advances in 2023: **GPU-level Trusted Execution Environments (TEE)** became available, extending confidential computing to AI workloads[13]. (NVIDIA has been working on GPU enclaves since ~2019 for a client; Google's TPUs still lack support as of 2025.) These TEEs allow AI models to run inside encrypted, isolated memory regions on accelerators, protecting both model weights and user data during inference. *Why it matters:* Trustworthy AI isn't just about the model's logic – it's also about *securing the infrastructure* so the model cannot be manipulated or leak sensitive information. The fact that *confidential AI inference is now technically feasible on modern hardware* is a big enabler: for instance, a hospital could run an AI on patient data in the cloud with guarantees that no one (not even the cloud provider) can peek at the data or altered model. This development addresses the "unauthorized access" and "cryptographic infrastructure" element of the ART description, moving it from theory toward implementation.
123. **"Constitutional AI" for Value Alignment – Bai et al. (Anthropic), arXiv preprint (peer-reviewed at ICLR 2023) – Dec 2022. Finding:** Introduced a novel *self-alignment* method for AI models using a fixed set of human-provided principles (a "constitution"). The team trained a large language model to be harmless and helpful **without extensive human feedback**: the AI model was made to *generate critiques of its own outputs and improve them* following the given principles[14]. They then used a form of reinforcement learning where the *reward signal came from an AI evaluator (model-generated preferences) rather than human labels*, called "RL from AI Feedback (RLAIF)"[15]. The result was an assistant that *refused unsafe or unethical requests by citing its principles*, yet did so in a non-evasive, transparent manner (explaining its objections). *Why it matters:* This showcases a viable path to *embedding explicit rules and values into AI behavior* – essentially aligning the AI internally with human-defined ethics. It's significant because it achieved alignment with far fewer human interventions, hinting at scalable solutions for future, more powerful AI. This addresses the core of the ART: making AI behavior *controllable and value-driven by design*. The work is being deployed in real systems (Anthropic's Claude chatbot), indicating a transition from research to practical tooling for alignment.
124. **Neural Network Verification Competition (VNN-COMP 2023) – Brix et al., arXiv (report) – Dec 2023. Finding:** The 4th International Verification of Neural Networks Competition featured 7 teams and established common benchmarks for formally verifying properties of neural nets[16]. Notably, the community has standardized on exchange formats (ONNX for models and VNN-LIB for specs) and used an *automated evaluation pipeline* on

cloud instances to compare tools fairly[17]. Tools showed increasing capability to prove properties on diverse networks (e.g. robustness within certain input bounds, safety of control decisions, etc.). *Why it matters:* Formal verification of AI, once very nascent, is now *organized and progressing year-over-year*. The existence of such competitions signals that the field has moved from isolated academic ideas to a coordinated effort to push capabilities (e.g., handling larger networks or more complex specs each year). It's an indicator of plausibility that eventually, at least in well-specified scenarios, we will have **AI components with mathematically provable guarantees** – a cornerstone for high-assurance systems. This evidence shows the underlying methods are maturing, though they may still be computationally expensive or limited to smaller models today.

125. **Industry Investment in Trustworthy AI (AI Security) – Cisco acquisition of Robust Intelligence, reported by S&P Global – Aug 2024. Finding:** Cisco Systems acquired Robust Intelligence (a startup specializing in AI robustness and validation) for an estimated **\$350M**[18]. Robust Intelligence's platform provides automated "AI firewall" and stress-testing of models to catch vulnerabilities. The report notes this is one of the first major tech acquisitions in the AI assurance space, and it cites enterprise survey data: "*security for generative AI*" is the #1 emerging technology priority in security teams, with **23% of organizations already running pilot projects** and many more planning to in the next 1–2 years[19]. *Why it matters:* This is strong evidence of *commercial and competitive momentum* toward trustworthy AI solutions. Multiple well-capitalized actors are now in the fray – not only startups with dedicated products, but big incumbents like Cisco, IBM, Microsoft, Google investing via acquisitions or internal R&D. The market pull (driven by client demands and fear of AI failures) is validating that these technologies aren't just academic; they are becoming *standard components of AI deployments*. The acquisition also suggests that robust AI tools are nearing a level where they can be *packaged and integrated into enterprise workflows at scale*, heralding a new industry segment focused on AI risk management.

126. **Maturity score (1–7) and reasoning**

**Final Score: 5 (out of 7)** – *The overall technology bundle "Trustworthy AI Systems" is at a solid mid-to-late development stage. Many pieces have progressed beyond proof-of-concept (Level 3) and even pilot deployments (Level 4), entering an era of active productization and competition (Level 5). However, full integration and ubiquity are not yet achieved, and some sub-components remain less mature, keeping the bundle shy of Level 6.*

- **Why not lower:** We have **concrete evidence ruling out Levels 1–4**. The fundamental feasibility is long proven (Level 1/2) – e.g. we have lab validations for robust learning, bias mitigation, etc., and even formal verifications on small cases. We've also seen **laboratory prototypes solving key barriers (Level 3)**: for instance, the 2024 robust model that achieved 71% robust accuracy[1][2] removed a major blocker by showing large models can be trained to resist adversarial attacks. **Working prototypes in operational environments (Level 4)** are clearly present: the IDx-DR medical AI running autonomously in clinics is essentially a proof-of-concept deployed under real conditions (with regulatory approval)[7][8]. Likewise, multiple *comprehensive frameworks* (Microsoft's, IBM's, etc.) have been rolled out to practitioners to meet real-world needs for explainability and monitoring, indicating functionality meeting commercial requirements. These achievements show that *no single piece of the puzzle is purely theoretical anymore – each has seen practical demonstration*.
- **Why not higher: Level 6 (products in widespread delivery)** is on the horizon but *not fully realized across the board*. While some trustworthy AI features are included in products (e.g. cloud ML services offering bias tools, or autonomous AI diagnostics in healthcare), we can't

say the *complete vision* is delivered at scale yet. For example, **formal verification** of AI remains mostly a research endeavor – we don’t yet have neural networks routinely shipping with provable guarantees (they are *starting* to for narrow cases[17], but it’s not mainstream). Similarly, **true self-monitoring AI with broad self-correction** is still limited – as evidence, even though explainability tools exist, their effectiveness in fostering trust can vary and sometimes underperform expectations[12]. And importantly, today’s powerful AI models (like large language models) still exhibit occasional brittleness or unpredictable outputs, meaning *robustness and alignment are not “solved” problems* in practice, and further R&D is ongoing (sign of not yet Level 6 where issues are largely ironed out and products reliably meet stringent demands). Additionally, the need for high-quality data, policy governance, and the overhead noted in the ART description is indeed being encountered as a friction in scaling these solutions – organizations are grappling with implementing these layers, suggesting the technology hasn’t yet become plug-and-play universally.

- **Indicators of Level 5:** We see **multiple well-capitalized actors racing** to deliver Trustworthy-AI-enabling products. The Cisco–Robust Intelligence deal in 2024 is a prime example, showing that big players are investing heavily to obtain these capabilities[18]. Startups focusing on AI auditing, fairness, and safety have attracted significant funding, and big cloud providers have launched competing responsible-AI toolsets – a clear sign of a competitive market forming (a hallmark of Level 5). Moreover, *standards and regulations are coalescing* (e.g. NIST RMF, impending EU AI Act), effectively forcing the hand of vendors to build compliance features – this accelerates product development and deployment. We also see that many of these subsystems (*robustness, explainability, monitoring*) are being *integrated into enterprise workflows* now (via toolboxes and platforms), indicating that production prototypes are being actively trialed and refined in real deployments. Progress is indeed **fast-paced**, as the rubric describes for Level 5: the timeline from research to product has shortened (e.g., Anthropic’s 2022 alignment method was incorporated into a commercial chatbot the next year).
- **Sub-component breakdown:** If we score elements individually, **some elements are quite mature (Level 6)** – e.g. *Explainability and bias mitigation tools* are delivered as part of major cloud services and used in customer-facing AI solutions today. *Model monitoring and data lineage* (MLOps governance) are also well into Level 6 in enterprise AI deployments, as evidenced by widespread availability[5][6]. Meanwhile, **other elements linger around Level 3–4** – e.g. *formal verification of AI* is still mostly at prototype stage (lab competitions, initial aerospace trials) without industry-wide deployment, and *general AI self-correction or strong value alignment* remains at proof-of-concept (we have encouraging demos[14][15], but not yet a guarantee in every deployed AI). **Robust adversarial resilience** is roughly Level 4 – researchers have demonstrated it in principle at scale[1][2], and some robust models are used in security-sensitive fields, but it’s not yet standard for all AI systems. Considering this mix, the *overall bundle’s maturity is an aggregate in the Level 5 range*. The more developed aspects show that trustworthy AI *can* be productized, and the less developed ones are actively being worked on with strong incentives to catch up (especially as regulation creates urgency). We choose the **average-based score of 5**, reflecting that many (though not all) pieces have moved into the stage of intense engineering, commercialization efforts, and early adoption.

**In summary,** *Trustworthy AI Systems* as a unified vision is well past the exploratory stage – it’s becoming a competitive requirement and is being partially delivered in practice (hence above Level 4). But achieving the full, integrated ideal (where AI is universally safe, auditable, and self-monitoring by default) will require a bit more time and advancement, which is why we stop at **Level 5**. The ongoing evidence – from field deployments to corporate investments – strongly suggests that within the next few years we’ll see further convergence toward Level 6, as isolated trustworthy AI capabilities consolidate into standard product features and

industry norms. For now, however, the technology's **maturity is best characterized as “proven in parts, with active expansion toward comprehensive solutions.”**

## ART 03.018 Automated Machine Learning (AutoML)

### 1. ART extraction

**A. Primary capability** – The ART promises a “*model and agent factory*” that can **automatically design, train, and deploy ML models and agents with minimal human input**. Key capabilities include: - **End-to-End Model Building**: Automatically selecting model architectures, hyperparameters, and training pipelines to produce high-performing predictive or generative models without manual tuning. - **Autonomous Agent Training**: Given simulators or interaction data, automatically training reinforcement learning (RL) agents through trial-and-error (including safe exploration and sim-to-real transfer) to achieve specified goals.

**B. Key sub-components / variants** – This technology bundle encompasses several threads: - **Neural Architecture Search (NAS) & Hyperparameter Optimization (HPO)**: Algorithms to automatically find optimal model architectures and training settings[1]. This extends to *AutoDL* for deep nets and *AutoRL* for policy networks[2]. - **Automated Data Preprocessing & Feature Engineering**: Pipelines that clean and transform raw data, engineer features, and handle data splits with minimal human guidance (currently partial in many AutoML tools[3]). - **AutoML for Reinforcement Learning (AutoRL)**: Methods to automate the design of RL training (reward shaping, environment generation, algorithm selection) – a nascent area tackling RL-specific challenges[4][5]. - **Continuous Model Monitoring & Adaptation**: Systems that monitor deployed models for performance drops or data drift and can trigger retraining or rollback to maintain robustness over time (often integrated in modern AutoML platforms[6]). - **Human-ML Interface (No-Code ML)**: User interfaces (dashboards, natural language prompts, APIs) enabling non-experts to request and deploy models/agents without coding, effectively democratizing model creation[7].

**C. Maturity indicators** – Evidence of maturity would include: - **Peer-Reviewed Demonstrations**: Proof-of-concept AutoML systems that **match or exceed expert-designed models** on benchmark tasks (accuracy, efficiency) and solve previously intractable design problems[8][9]. - **Production-Ready Frameworks & Products: Multiple competing AutoML platforms available commercially** (cloud services, enterprise software) with growing user adoption[10][11]. Indicators include **customer case studies** showing reduced development time or improved outcomes via AutoML[12]. - **Scaling and Self-Management**: AutoML solutions managing **large-scale workloads** (big data, complex models) and incorporating features like automated drift detection, safety constraints, or self-tuning in production[6]. Field trials or deployments of AutoML-driven agents (e.g. in robotics or finance) would further demonstrate maturity. - **Investment and Competition**: Significant **R&D investment by major tech companies and startups**, with dedicated conferences (e.g. an AutoML Conference since 2022) and an expanding market size, signaling that the technology is moving toward mainstream use[13].

## 2. Evidence (10–20 recent, reliable sources)

- Automated RL survey – Parker-Holder et al., JAIR (2022):** “*Automated Reinforcement Learning (AutoRL): A Survey and Open Problems.*” **Venue:** Journal of AI Research, vol. 74, 2022. **Findings:** Surveys how AutoML techniques are being extended to RL, noting that **AutoML has shown promise in automating RL training design**, with initial successes in domains from RNA sequence design to Go gameplay[4]. AutoRL is identified as an *emerging research area* addressing RL-specific challenges, underlining the plausibility of an “agent factory” but also that additional research is needed for full maturity[4][5].
- AutoML hyperparameter optimization – Vincent & Jidesh, Scientific Reports (3/2023):** “*An improved hyperparameter optimization framework for AutoML using evolutionary algorithms.*” **Venue:** Scientific Reports (Nature), Mar 2023. **Findings:** Proposes enhancements to Bayesian HPO in AutoML by integrating genetic algorithms, differential evolution, and CMA-ES for optimizing the acquisition function. In experiments on image classification, these evolutionary tweaks **significantly improved model performance compared to standard Bayesian optimization**[11], highlighting ongoing advances that make AutoML model tuning more efficient and effective (thus increasing the feasibility of fully automated model search).
- AutoML framework benchmark – Eldeeb et al., Expert Systems with Applications (6/2024):** “*AutoMLBench: A comprehensive experimental evaluation of automated machine learning frameworks.*” **Venue:** ESWA (peer-reviewed), June 2024. **Findings:** Benchmarked **six AutoML frameworks** (Auto-WEKA, Auto-sklearn, TPOT, Recipe, ATM, SmartML) on 100 diverse datasets[14]. It finds that these tools can reliably **produce models competitive with hand-tuned models**, given sufficient time budgets. Key insights include: small search spaces with top algorithms yield near-optimal results, meta-learning helps cold-start on short budgets, and **ensemble models consistently improve accuracy**[15]. This cross-framework study indicates a *maturing ecosystem* of AutoML solutions, with multiple implementations in active use and known design trade-offs (time vs. performance, etc.), supporting the technology’s plausibility and emerging standardization.
- AutoML for small data & usage trends – Conrad et al., Scientific Reports (11/2022):** “*Benchmarking AutoML for regression tasks on small tabular data in materials design.*” **Venue:** Scientific Reports (Nature), Nov 2022. **Findings:** Evaluated AutoML on small (~<1000 samples) science datasets. Concludes that **AutoML is highly competitive with manual model optimization even with limited training time**[16], often matching expert-tuned results, which underscores its practicality. Importantly, the paper notes **widespread adoption by practitioners**: a 2021 Kaggle survey found ~58% of data scientists use AutoML tools (and rising)[17]. However, it also observes that current AutoML tools mostly automate model/parameter selection, whereas **data preprocessing, feature engineering, and model interpretability remain only partially automated** in practice[3]. This mixed finding shows the field has *proven core capabilities* (model search/tuning) and active usage, while pointing out remaining gaps (full pipeline automation and self-explanation).
- AutoML & LLMs (vision paper) – Tornede et al., arXiv preprint (6/2023):** “*AutoML in the Age of Large Language Models: Current Challenges, Future Opportunities and Risks.*” **Venue:** arXiv preprint (under review), June 2023. **Findings:** An expert roadmap discussing how AutoML and large language models (LLMs) can mutually enhance each other. It states that **AutoML has achieved remarkable success over the last decade, evidenced by heavily-used open-source frameworks (Auto-sklearn, AutoGluon, etc.) and commercial tools**[18]. This underscores that the core AutoML idea is already validated and in wide use. At the same time, the authors note that *current AutoML methods are not yet equipped to fully automate the entire lifecycle of massive LLMs* due to extreme compute demands and multi-stage training

complexities[19]. This source reinforces that for typical problems AutoML is quite mature, while the frontier (applying it to state-of-the-art AI like billion-parameter models) is an ongoing challenge – aligning with the ART’s constraint that large data/compute requirements remain a bottleneck.

- **AutoML surpassing human-designed algorithms – Fawzi et al. (DeepMind), *Nature* (10/2022):** “*Discovering faster matrix multiplication algorithms with reinforcement learning.*” **Venue:** *Nature*, Oct 5, 2022. **Findings:** DeepMind’s “AlphaTensor” agent used AutoML-like search (via deep RL) to **automatically discover new matrix multiplication algorithms more efficient than any human-derived algorithm**[8]. Notably, it found a 4×4 matrix multiply method that improves on Strassen’s classical algorithm – the first such improvement in 50 years[20]. This dramatic result demonstrates the *scientific plausibility* of automated methods designing superior solutions in very complex search spaces. AlphaTensor is a specific case (algorithm design), but it epitomizes the ART’s claim that automated systems can “reach beyond human intuition”[21] – lending credibility to AutoML’s ability to explore model/agent design spaces at superhuman scale and thoroughness.
- **Automated algorithm deployed in practice – Mankowitz et al. (DeepMind), *Nature* (6/2023):** “*Faster sorting algorithms discovered using deep reinforcement learning.*” **Venue:** *Nature*, June 7, 2023. **Findings:** DeepMind’s “AlphaDev” system autonomously discovered improved sorting algorithms via reinforcement learning. **The AI-found algorithms outperformed long-standing human benchmarks and have been integrated into the LLVM C++ standard library**[22], replacing the prior sorting routine. This real-world deployment is a milestone: an automated design not only matched but *surpassed* human solutions and was trusted enough for production use. It underscores that automated machine learning/algorithm design is transitioning from lab demos to practical impact, signaling a high maturity for the underlying approach (at least in constrained domains). It also highlights the importance of guardrails: such systems were carefully verified (proofs of correctness were required)[22], echoing the ART’s note that governance and validation remain essential even as AutoML capabilities grow.
- **Industry AutoML platform (Google) – Encora Tech Blog (10/2023):** “*Unlock the Power of AutoML with Google’s Vertex AI.*” **Type:** Industry technical blog (Encora Inc.), Oct 2023. **Details:** Describes Google Cloud’s Vertex AI AutoML services. Emphasizes a **no-code interface that “puts the power of machine learning in the hands of non-experts,”** enabling users without ML expertise to build image, text, or tabular models via a few clicks[7]. It also notes that Vertex AI provides “**robust monitoring and management tools**” to ensure models continue to perform optimally as data evolves[6] – reflecting automated retraining/adjustment capabilities. This source exemplifies a *commercially delivered AutoML product*: it offers on-demand scalability, covers a wide range of use cases, and includes MLOps features like drift detection alerts. The existence of such platforms (from Google and others) indicates that AutoML for standard supervised tasks is already at a product stage, being actively used in industry to reduce specialist labor needs.
- **Market growth and case studies – Market report (ResearchAndMarkets via PRNewsWire, 5/2023):** “*Global Automated Machine Learning (AutoML) Market Report 2023: Increasing Need for Accurate Fraud Detection Drives Growth.*” **Type:** Market analysis report (press release summary), May 2023. **Details:** Estimates the **AutoML market at ~\$1.0 billion in 2023, projected to reach \$6.4 billion by 2028** (44.6% CAGR)[13], highlighting rapid growth. It attributes demand to industry needs like customer personalization and fraud detection in finance (BFSI sector being a major adopter)[23]. The report cites concrete **enterprise case studies**: e.g., *Consensus Corp.* cut model deployment time from “**3–4 weeks to 8 hours using**

**AutoML**\*\*[12], and PayPal used H2O Driverless AI to strengthen fraud detection[11]. Numerous vendors are named (Google, AWS, Microsoft, DataRobot, H2O.ai, etc.[24][25]), showing a competitive landscape. This evidence demonstrates that multiple well-capitalized actors are delivering AutoML tools to real customers, across various industries\*\*, and achieving notable efficiency gains – a strong indicator of advanced maturity (moving from experimental to widely operational).

*(Additional references above also support these points: e.g., AutoML competition wins by academic groups[26] and the formation of an annual AutoML Conference (since 2022) illustrate the field's momentum, though they are not individually listed.)*

### 3. Maturity score (1–7) and reasoning

#### A) Final maturity score: 6 (out of 7).

**B) Justification of score:** AutoML as a whole has **progressed into a product-delivery and scaling phase, albeit not yet fully ubiquitous**. The evidence shows that we have **moved beyond prototypes** – multiple independent AutoML frameworks and services are operational and competing, with **major tech companies and startups delivering products to customers (characteristic of Level 6–7)**. For example, Google's Vertex AI AutoML, Amazon's AutoGluon/SageMaker Autopilot, DataRobot, H2O Driverless AI, etc., are in active enterprise use, and the AutoML market is valued around \$1B with fast growth[13]. This widespread deployment and competition strongly *rule out lower maturity levels* (Levels 3–4, which correspond to mere prototypes or single pilots). Furthermore, **real-world impact has been demonstrated**: AutoML has enabled non-experts to achieve results comparable to expert data scientists[17][9], and even produced algorithmic solutions beyond human designs in certain cases[8][22] – evidence that meets or exceeds the expectations of Level 5 (PoC proven clearly beneficial).

However, a few factors stop us from assigning the maximum score of 7: **not all aspects of the ART vision are equally mature or widely adopted yet**. Notably, the **“agent factory” extension (AutoRL)** is still in early-stage research (labs have demonstrated automated RL tuning[4], but there is no off-the-shelf product that lets non-experts train arbitrary autonomous agents safely with full automation). Similarly, **full automation of the entire ML lifecycle (including data cleaning, feature engineering, and continuous self-evolution of models) is only partially realized** – current AutoML tools still require human oversight for data preparation or confirmation of model changes[3]. These gaps mean the field as a whole hasn't reached the breadth of deployment and *trusted autonomy* implied by Level 7 (which would require AutoML to be as routine and self-sustaining as, say, automated compilers or database systems in IT). Governance concerns (bias, safety) also present ongoing challenges[27][28], and their resolution will likely accompany the final push to Level 7.

In summary, **AutoML's core functionality for standard ML tasks is at a high maturity (even approaching Level 7 in those domains), while newer extensions (like automated reinforcement learning and fully self-managing pipelines) lag behind**. Given this mix, we assign an overall **Level 6**: - Level 6 is justified by evidence of products “being delivered to customers in increasing amounts” with expanding applications and internal financing. Indeed, multiple vendors are selling AutoML solutions, and adoption is rising across finance, healthcare, etc.[29][30]. Companies have invested heavily, indicating confidence in near-term returns. - *Why not Level 7?* Reaching 7 would require **broad, rising demand across**

**essentially all sectors and fierce competition solely driven by market forces**, with the technology largely “solved” except ongoing incremental improvements. **While demand is growing, AutoML is not yet a default approach everywhere** – some organizations still rely on manual ML due to trust or complexity issues[28]. Moreover, the cutting-edge functions (automating complex agent behaviors, handling any scenario with minimal human input) are not fully commoditized yet. The need for expert validation (to handle bias, explainability, data nuances) means AutoML hasn’t entirely replaced human ML engineers, especially for high-stakes or very novel tasks.

**C) Sub-component breakdown:** To support the aggregate score, we note sub-technology maturity: - *AutoML for supervised learning (model/feature selection, HPO, NAS)*: **Level 7**. Multiple **competing products** from well-capitalized companies are on the market, with a wide user base. Evidence: e.g., Google, Amazon, Microsoft cloud AutoML services and open-source libraries are widely used, and ~58% of data scientists report using AutoML tools[17]. These systems reliably deliver value (sometimes super-human model performance) in vision, NLP, and tabular tasks, indicating a near-full commercialization. - *AutoML for reinforcement learning (agents/policies)*: **Level 3–4**. Demonstrated in research prototypes and some benchmarks (lab successes like AutoRL tuning for games[31], AutoML-designed algorithms in controlled settings[22]), but **no general commercial AutoRL platform yet** for non-experts. It’s at the functional prototype stage (proof-of-concept algorithms exist, motivating investment, but production viability and safety are still being proven). - *Automated data pipeline & model management (MLOps automation)*: **Level 5**. Early versions are integrated into products (e.g., Vertex AI’s automated monitoring and pipeline triggers[6]). There are proofs-of-concept in industry that model retraining can be automated on drift detection. Yet, most deployments still require human oversight to validate retrained models or to set constraints. The functionality exists and clearly adds value (e.g. greatly reducing model maintenance time), and major actors are actively developing it, but it’s not entirely “fire-and-forget” yet.

Given these varied sub-scores, we weight by their importance to the overall ART vision. **The core value – automating model development – is at the highest maturity (driving the high score), while the less mature aspects are emerging but not dominant in usage.** Thus, averaging the bundle might yield a 5–6, but since the primary capability is already broadly realized, we lean to **Level 6**. This score captures that AutoML is **no longer speculative** – it’s a rapidly scaling technology with proven benefits – but also acknowledges that *the ultimate vision of a fully autonomous, self-evolving “AI factory” is just shy of fruition*, likely to be achieved as the newer components catch up in the coming years. The next jump to Level 7 would be warranted once we see truly autonomous end-to-end ML systems widely trusted in production (including automated agents and self-correcting models), a milestone on the horizon but not uniformly reached as of today.

## ART 03.019 Collaborative Multi-Agent AI

### 1. ART extraction

**A. Primary capability:** *Collaborative multi-agent AI* enables many intelligent agents (software or robots) to work as a coordinated whole. They **share information and negotiate roles in real time** to achieve common goals, instead of operating in isolation. This promises **parallel, resilient task execution at large scales** – for

example, covering wide areas with swarms of sensors/robots, handling numerous small tasks simultaneously, and **continuing operation despite individual failures** (graceful degradation).

### B. Key sub-components / variants:

- **Distributed sensing & actuation:** Heterogeneous agents (from fixed IoT sensors to mobile robots and cloud services) form a network, **exchanging data over wireless links and APIs**. They maintain shared world models (e.g. common maps or task queues) that any agent can update and use.
- **Communication & networking:** Robust *ad hoc* mesh networks and protocols are needed to connect dozens or hundreds of agents. Systems must avoid radio interference and congestion when many devices communicate at once, often leveraging **decentralized networking** and local broadcast techniques for scalability.
- **Coordination algorithms:** A mix of pre-programmed rules and AI/ML (e.g. multi-agent reinforcement learning) governs cooperation. Agents dynamically allocate tasks, form sub-teams, plan paths, and adapt to changes **without a central controller micromanaging each unit**. They can negotiate roles or share intent through messages, and even use learned strategies from collective experience.
- **Human-swarm interface:** Dashboards, voice/text commands, and supervisory control tools allow humans to set high-level objectives, impose safety constraints, and override or adjust behaviors. Hierarchical control lets human operators intervene at different levels of detail (from whole swarm to individual agent) as needed.
- **Safety & fault-tolerance:** Mechanisms for fail-safe behavior are critical. Agents handle **uncertain sensing and dropouts** gracefully – e.g. defaulting to safe modes if data is lost, redistributing tasks if a unit goes offline. Redundancy and cross-validation (agents cross-check each other's observations) mitigate errors and increase reliability.
- **Variants by domain:** *Swarm robotics* (drones, autonomous vehicles, robots cooperating in physical tasks) vs. *distributed digital agents* (software bots/services coordinating in cyberspace) are two extremes, often combined. Some systems emphasize **swarms of inexpensive robots** for field operations (e.g. drone swarms, fleets of farm robots), others might involve **millions of micro-agents** in IoT networks or cloud simulations. All share the core challenge of scalable, distributed decision-making.

**C. Maturity indicators:** We expect evidence such as: **large-scale field trials or demos** (e.g. dozens of robots teaming up autonomously in real environments); **prototypes solving coordination challenges** (like consensus with limited comms, dynamic task allocation); **early commercial deployments** or pilot programs (e.g. robot swarms used in industry, warehouse fleets, agricultural robot teams); **competition among major players** (multiple well-funded companies or military programs racing to develop swarm systems); **standardization efforts or platforms** for multi-robot coordination; and eventually **shipping products** with multi-agent autonomy (with growing customer adoption and scaling production). Signs of progress include achieving reliable performance beyond single-robot limits (coverage, efficiency) and falling costs per agent enabling larger deployments. Field robustness (handling communication loss, complex environments) and integration into human workflows (use of supervisory UIs) are key hurdles being overcome in recent projects.

## 2. Evidence (10–20 recent, reliable sources)

3. **Swarm robotic cooperation advantages – Cai et al., Neurocomputing (Survey, peer-reviewed), 09/2024.** *Overview:* Surveys the state of multi-agent *robotic swarm* systems, highlighting that compared to a single robot, a swarm of agents can coordinate via information sharing to achieve a **wider monitoring range, flexible organization, and strong reconfiguration** (adaptability)[1]. It reviews key technologies for collaborative tasks (e.g. target search, task allocation, path planning) in multi-robot swarms and notes broad applications from environmental monitoring to rescue and military use. *Why relevant:* Confirms the fundamental plausibility and motivation for multi-agent AI – leveraging collective behavior yields capabilities (coverage, resilience) unattainable by lone agents, and these principles are being actively researched across domains.
4. **Decentralized multi-UAV team in DARPA challenge – Petrlík et al., Field Robotics (peer-reviewed), 01/2023.** *Finding:* Demonstrated a **fully autonomous, decentralized team of drones** that cooperatively explored a complex underground environment in the DARPA Subterranean Challenge finals[2]. The system used novel mapping techniques to enable multi-robot cooperation under very low-bandwidth communications[3], allowing the UAVs to share a compressed map and coordinate without constant contact. It proved robust in a harsh real-world setting (dark, GPS-denied tunnels), where the drones collectively searched for objects. *Why relevant:* This is a concrete proof-of-concept of collaborative multi-agent AI in the field – multiple robots formed an ad-hoc team, distributed themselves to map and search, and succeeded **without central control**. It validates the feasibility of key constraints mentioned (limited connectivity, need for on-board decision-making) and shows the technology working in a realistic mission scenario.
5. **AI-driven drone swarm (70-unit concept) – Edge Group (Halcon), Defense News (industry news), 02/2022.** *Revealed:* A UAE defense contractor unveiled the “Hunter 2-S” swarming drone system, capable of launching **36 drones (with plans for up to 70)** from a single vehicle[4][5]. The drones use an algorithm to communicate over a main channel and share information about targets, dividing into sub-groups to engage multiple targets collaboratively[6]. A first live demonstration launched one drone from a tube (wings deployed and it flew successfully), with full-system flight tests planned for 2023 and production slated by 2025[7]. *Why relevant:* This illustrates a near-term *pre-production prototype* of a coordinated multi-agent system. It shows industry investment in architectures for dozens of agents that coordinate targeting and maintain formations autonomously. The roadmap (demo → testing → production) and interest from armed forces indicate both technical feasibility and a drive toward real-world deployment, underscoring rapid maturity in multi-agent coordination (at least in specialized domains like defense).
6. **Multi-robot search & rescue trial – Deep Robotics (China), IoT World Today (trade news), 03/2023.** *Reported:* Five autonomous quadruped robots (Deep Robotics “Jueying X20” units) were successfully trialed as a team in a 3,000 m<sup>2</sup> simulated disaster environment[8]. In eight different search-and-rescue missions, the **team of five robots shared information over a wireless mesh** network and used an in-house multi-robot exploration algorithm to coordinate their coverage[9][10]. They split up to evenly cover the area, communicated only the most essential data (to reduce bandwidth use), and collaboratively located targets (e.g. victims or hazardous objects). Each robot had Lidar and cameras for sensing, and the cooperative strategy improved speed and accuracy of search outcomes. *Why relevant:* This demonstrates a *field trial* by an industry player showing that multi-agent robotics can perform a complex task (searching a building) more efficiently as a group. It validates the plausibility in a civilian context and shows attention to practical issues like limited bandwidth (they optimized communication by sharing only simple, useful info[9]). The trial’s success suggests the

approach is moving toward real deployment to augment or replace humans in hazardous response scenarios.

7. **AI negotiates in multi-agent strategy game – Meta (FAIR) CICERO, Science (peer-reviewed), 11/2022.** *Achievement:* Meta AI's CICERO is the first AI agent to reach **human-level performance in the 7-player board game Diplomacy**, which requires natural language negotiation and alliance formation[11]. CICERO combined a language model with strategic reasoning so it could coordinate plans with multiple human players via dialogue. In 40 online games, it doubled the average score of human participants and ranked in the top 10%[12]. Crucially, the AI engaged in convincing human-like negotiation – forming agreements and adjusting strategy when partners cooperated or betrayed. *Why relevant:* Diplomacy is a notoriously complex multi-agent setting (no single winner can succeed without collaboration). CICERO's success demonstrates the feasibility of *software agents that negotiate roles and joint strategies* with others in real time. It provides evidence that AI systems can coordinate and cooperate in open-ended environments, not just follow pre-set rules – a key aspect of the ART. This represents progress in the “purely digital agents” side of collaborative multi-agent AI, highlighting advanced capabilities like communication and learning of trust, which underpin plausibility for broader applications.
8. **Autonomous satellite swarm experiment – NASA Starling mission, Small Sat Conference (tech report), 08/2024.** *Results:* NASA's Starling mission launched four small satellites in July 2023 to test autonomous swarm cooperation in orbit. The swarm successfully established a **mobile ad-hoc network** between satellites and exchanged data peer-to-peer (using the B.A.T.M.A.N. mesh protocol)[13]. It also ran a distributed decision-making experiment: each satellite made observations (ionospheric measurements) and the group reached **consensus on an optimal joint data-collection strategy**, then adjusted their observation plans *autonomously* based on that consensus[14]. Additionally, the swarm performed coordinated maneuvers (formation flying) with minimal ground control, demonstrating the ability to maintain formation as a group. *Why relevant:* This is a cutting-edge demonstration of multi-agent AI in a challenging domain (space) where continuous connectivity and central control are impractical. The satellites collaborated by sharing sensor data and computing consensus decisions – exactly the kind of “negotiate roles and adapt collectively” behavior described in the ART. The success of Starling's experiments shows that even with only 4 agents, the architecture and algorithms scale to complete tasks cooperatively and robustly (networking, distributed sensing, and coordinated actuation in this case). It paves the way for larger “swarms” of spacecraft and validates the robustness of multi-agent networks under real-world conditions (latency, link disruptions, etc.).
9. **Fleet of farm robots in commercial use – SwarmFarm Robotics (Australia), Advance Queensland report (gov't innovation case study), 02/2025.** *Data:* SwarmFarm, an agricultural robotics company, has **deployed 135+ autonomous robots** on farms across Australia, collectively covering over 6 million acres of operations[15]. Their approach uses **smaller, smarter machines working together** rather than one big machine – e.g. multiple lightweight rover units collaboratively weed or spray crops. This improves efficiency and reduces environmental impact (up to 80% less chemical usage) by targeting only where needed. The robots operate with shared digital maps of the field and coordinate to ensure complete coverage without gaps or overlap. *Why relevant:* This provides real-world evidence that coordinated multi-robot systems are transitioning into **actual products and scaling deployments**. SwarmFarm's large number of units in the field (and millions of acres serviced) indicates that the multi-agent concept is not just a lab demo – it is delivering value to end-users (farmers) today. The fact that a *single operator can oversee multiple farm robots* via a central interface addresses the human-swarm interaction component. This example

underscores the commercial viability and growing adoption of multi-agent AI in industry, as well as the economic drivers (labor savings, reduced chemicals) making it attractive.

10. **Heterogeneous robot team at robotics challenge – Lee et al., arXiv preprint (KAIST Team OCEAN), 10/2024.** *What was done:* Demonstrated an **integrated aerial-ground robotic team** in the 2023 MBZIRC Maritime Grand Challenge. A drone autonomously deployed a legged hexapod robot onto a target vessel (and retrieved it) in a GPS-denied maritime environment[16]. The UAV and hexapod coordinated their actions: the drone provided long-range mobility and vision, while the ground robot handled precise tasks on the moving ship's deck. They used sensor fusion (optical flow, LiDAR, etc.) for localization instead of GPS, and a winch mechanism for the drone to lower and raise the hexapod. The system was **successfully validated in field tests** during the competition, where the KAIST team placed 2nd overall[17][18]. *Why relevant:* This showcases a complex, *ad hoc* multi-agent team with heterogeneous members – exactly the kind of dynamic teaming the ART describes. The UAV and UGV (hexapod) had to communicate and coordinate in real time under challenging conditions (moving platforms, no external positioning). The fact this was done in a competitive setting and worked reliably enough to earn a top prize speaks to the rapid progress in multi-agent autonomy. It also expands the application space (maritime security and rescue, in this case), showing the versatility of the approach. The example highlights how agents with different capabilities can form a team to overcome each other's limitations (flying robot + walking robot), a key advantage of multi-agent systems.
11. **Large Language Models to coordinate robots – Liang et al., arXiv preprint (research, NYU Abu Dhabi), 02/2025.** *Insight:* Proposes and tests a novel multi-robot collaboration framework that integrates **Large Language Models (LLMs)** into the decision loop. The authors note that recent work uses LLMs to improve multi-agent coordination – e.g. by breaking down complex tasks for different robots, assigning roles, and enabling coalition formation through dialogue[19]. Building on this, they introduce a “retrospective actor-critic” approach: one LLM-based module generates plans for the robots (the Actor) and another LLM-based module critiques the outcome and provides feedback to refine the next iteration (the Critic). In simulated trials, this method significantly improved the team's task performance and adaptability in dynamic scenarios[20]. *Why relevant:* This represents a cutting-edge development in the algorithms enabling collaborative AI. By leveraging LLMs (which are adept at communication and reasoning), researchers are tackling the complexity of coordination and flexible planning for multi-robot teams. The improved performance in simulations suggests that more **sophisticated, learning-driven coordination mechanisms** are becoming available – moving beyond rigid pre-programmed protocols. This makes multi-agent AI more plausible and scalable, as agents can communicate in natural-like language and adjust strategies on the fly. It also directly addresses one challenge in the ART description: mixing data-driven models (here LLMs and RL) with rules to allow dynamic teamwork.
12. **Swarm intelligence for multi-robot systems – Nguyen, AppliedMath (MDPI) (Review), 10/2024.** *Summary:* A comprehensive review of swarm intelligence algorithms as applied to multi-robot systems. It concludes that decentralized swarms (inspired by ants, bees, etc.) offer **robust, scalable, and flexible solutions** compared to traditional centralized robotics[21]. Swarm-based multi-robot systems have shown effectiveness in domains like search & rescue, environmental monitoring, agriculture, space exploration and warehouse logistics. Notably, swarms can **adapt to new challenges and continue functioning even if individual robots fail**, since there is no single point of failure[21]. The paper also discusses challenges such as real-time decision-making, communication failures, and unpredictable emergent behaviors, suggesting areas for future research (e.g. better real-time control and safety assurances in critical applications). *Why relevant:* This source provides authoritative context that **validates**

**the core value proposition** of collaborative multi-agent AI. It synthesizes evidence from many studies to affirm that multi-agent systems *do* improve efficiency and resilience, aligning with the ART's claims about reduced human bottlenecks and improved situational awareness through collective sensing. At the same time, it acknowledges the open challenges (communication and safety issues when scaling up), which helps gauge maturity – many theoretical benefits are confirmed, but ensuring reliability and control at massive scales (and in life-critical tasks) remains an active area of work.

### 13. Maturity score (1–7) and reasoning

**Score: 6 (Out of 7).** The overall maturity of *Collaborative Multi-Agent AI* is **high**, with early products and deployments already in use, though not yet fully ubiquitous.

**A. Justification (Evidence-to-rubric mapping):** Several pieces of evidence show that we have moved past basic theory and lab prototypes into the realm of **real-world prototypes, fast-paced development, and initial scaling of products**, which corresponds to rubric levels 4–6. Specifically, we see multiple **proof-of-concept demonstrations** in complex environments (DARPA SubT drones, NASA's Starling satellites, KAIST's maritime robots) – satisfying level 4 by showing functionality in real scenarios and solving key technical hurdles like decentralized control and limited communication[2][14]. Moreover, **well-capitalized actors are heavily invested and racing to deploy this technology** (level 5): for example, defense agencies and companies are testing drone swarms (UAE's Edge, US DARPA, etc.)[7], and big tech firms are tackling multi-agent learning (Meta's CICERO achieved a milestone in cooperative AI[11]). We have clear signs of **early commercial rollout (level 6)** in civilian sectors: the SwarmFarm case shows actual products (autonomous multi-robot fleets) delivered to paying customers with *hundreds of units deployed* and growing adoption[15]. Likewise, Amazon and other warehouse operators have tens of thousands of robots coordinating in their facilities (though not cited above, it's a known industry fact), indicating that multi-agent coordination is already underpinning large-scale operations. These facts rule out lower maturity levels decisively – this is far beyond theory (Lvl 1) or single lab demos (Lvl 2–3). The presence of **multiple competitors and expanding use-cases** (agriculture, logistics, defense, etc.) also shows we are at the cusp of wider scaling. Many projects are now internally or venture-funded for commercialization rather than just research grants, meaning the field is entering an implementation and growth phase.

**B. Why not a full 7:** We stop short of level 7 because the technology, while proven in various domains, is **not yet a seamless, ubiquitous commodity across all industries**. There are indeed competing products and rising demand in certain areas (e.g. multiple agri-robot startups, numerous drone swarm initiatives, various brands of warehouse robots), but collaborative multi-agent AI as a general capability is still in a maturing stage where integration and standardization are limited. Key challenges like reliable real-time coordination under extreme scales ("millions" of agents), guarantees of safety in unpredictable environments, and unified platforms or standards for multi-agent systems are **still being worked out**[21]. In other words, **the ceiling for this tech is very high and not yet reached** – we haven't seen millions of cheap agents working as one in practice, and human oversight tools for swarms are still evolving. To reach level 7, we'd expect to see *widespread deployment and routine use* of large-scale multi-agent systems across many sectors, with robust fail-safe performance and market ubiquity. That level of penetration will likely come in the next decade as the prototypes scale up. For now, the progress is recent and rapid but

somewhat siloed to specific pioneers and early adopters, keeping the overall maturity at a strong **6**.

**C. Sub-component breakdown:** This ART spans different application segments, which have slightly different maturity:

- *Industrial & commercial robotics swarms*: **Level 6–7**. Warehouse robot fleets and farm swarms are already delivering value at scale (hundreds or thousands of units) with multiple vendors in play, indicating near-product maturity[15]. (These drive the score upward; functionality here is largely the same – coordinating multiple mobile agents for efficiency – and it’s proven viable and cost-effective.)

- *Autonomous swarms in open, dynamic environments (drones, S&R, military)*: **Level 4–5**. Successful field trials and demos exist (autonomous drone teams in trials[2], live-fire tests of drone swarms, etc.), and governments are investing heavily, but routine deployment is just beginning. These systems work in principle, but need more validation for reliability and safety before full deployment (hence slightly lower maturity than factory/farm settings).

- *Multi-agent AI software (negotiation, distributed AI without physical robots)*: **Level 4**. Breakthroughs like CICERO show feasibility[11], but these are early examples in limited domains. The algorithms are advancing quickly (especially with new AI like LLMs[19]), yet widespread integration into business or society (e.g. multi-agent AI managing complex processes) is nascent.

Despite this variation, the *core capability* – agents acting jointly and adaptively – is essentially the same across these sub-fields. We therefore weight the overall score by the most advanced implementations, as they demonstrate the full potential of the technology. Given that **functional multi-agent systems are already on the market and scaling up (farms, warehouses)** and others are fast following, a composite score of **6** reflects that high maturity while acknowledging that some aspects (especially highly generalized coordination and ultra-large swarms) are a step away from the absolute peak of maturity. The next milestones (to reach level 7) would be broader adoption, standardized platforms, and consistent trust in multi-agent AI handling critical tasks at scale – all on the horizon but not yet uniformly achieved.

## ART 03.020 Quantum-Accelerated AI Systems

### 1. ART extraction

**A. Primary capability:** Quantum-accelerated AI systems combine quantum processors with classical AI hardware to tackle computational bottlenecks in AI tasks that are infeasible for classical computers alone. By offloading the most complex subroutines (e.g. searching large combinatorial spaces, parallel evaluation of many solutions) to quantum co-processors, these hybrid systems aim to achieve faster or more energy-efficient learning and decision-making on extremely large-scale data and models. From a user perspective, the AI applications run as usual (via APIs or software libraries), but behind the scenes an orchestration layer selectively invokes remote quantum hardware for those parts of the workload expected to see a quantum speedup or accuracy gain.

### B. Key sub-components or variants:

- *Quantum processing hardware:* The core enabler is quantum computing hardware (superconducting qubits, trapped ions, photonic processors, quantum annealers, etc.) with sufficient qubit count and fidelity. Both gate-model quantum processors and analog/annealing devices are pursued, often accessed over the cloud due to specialized cryogenic and control requirements. Error correction or mitigation technology is crucial to maintain coherence over the complex operations needed for AI tasks.

- *Hybrid algorithms and software integration:* New algorithms are developed to split AI workflows between classical and quantum parts – e.g. variational algorithms, quantum approximate optimization (QAOA), quantum-enhanced kernel methods, or quantum

Boltzmann samplers. Software frameworks (like TensorFlow Quantum, Qiskit Runtime, PennyLane, etc.) and middleware manage the interaction, scheduling quantum jobs within classical AI code. A “quantum gateway” or runtime environment handles data movement and synchronisation so that quantum acceleration is used seamlessly within existing AI pipelines[1][2].

- *Orchestration and HPC integration*: Because quantum resources are scarce and expensive, integration with high-performance computing (HPC) infrastructure is a key variant. This includes hybrid HPC clusters where GPUs/CPUs and QPUs (quantum processing units) are co-located or networked with scheduling systems (e.g. Slurm, CUDA-Q) to dispatch parts of AI workloads to quantum accelerators[3][4]. Various projects (IBM’s quantum-centric supercomputing, national labs’ quantum-HPC testbeds, cloud services like Amazon Braket) are converging on architectures to treat QPUs as special high-end accelerators within classical supercomputers.

- *Target problem classes*: Not all AI tasks benefit from quantum acceleration. The leading sub-areas are combinatorial optimization (e.g. scheduling, routing, feature selection, neural architecture search) where quantum algorithms (annealing or Grover-like searches) might find better optima faster[5]; large-scale sampling and generative modeling (e.g. Boltzmann machines, quantum-enhanced GANs) where quantum samplers explore complex probability distributions[6]; and certain linear algebra subroutines (like kernel evaluations or solving linear systems for machine learning) where quantum algorithms promise polynomial speedups. These define the initial use cases for hybrid AI platforms.

### **C. Maturity indicators:**

- *Scientific feasibility demonstrations*: Peer-reviewed experiments showing that quantum assistance can improve an AI-relevant task are a key indicator. For example, small-scale prototypes that achieve higher accuracy or speed than classical methods on certain classification or optimization problems[7], or hybrid models (quantum + classical) successfully trained on non-trivial data[6]. Such results bolster plausibility.

- *Prototype integration and field trials*: Evidence of quantum accelerators being integrated into real computing environments or tested on practical use-cases. This includes demonstrations of hybrid quantum-classical HPC clusters running AI workloads[3][4], cloud services offering quantum-enhanced ML functions (e.g. D-Wave’s feature selection plugin for scikit-learn[8][5]), or enterprise trials where quantum options are offered for specific optimization jobs. A working proof-of-concept system that industry users can experiment with marks maturity progress.

- *Competition and investment*: Multiple well-capitalized actors entering this space signal growing maturity. Major quantum hardware firms (IBM, Google, IonQ, D-Wave, etc.), big cloud/AI companies (Amazon, Microsoft) and government consortia (EU’s EuroHPC JU, U.S. DOE labs, etc.) all investing in quantum-AI integration efforts is a strong indicator. For instance, national labs partnering with industry to build quantum-accelerated supercomputing testbeds[9][10], and startups offering quantum machine-learning services, suggest the technology is moving beyond isolated research into a competitive development phase.

- *Performance crossing classical thresholds*: A critical maturity marker will be evidence of *quantum advantage* for useful AI problems – i.e. solving a problem faster or better than the best classical alternative. Early signs might be quantum solvers handling larger problem instances or achieving higher solution quality than classical heuristics in optimization tasks[11]. Reaching this point, even on narrowly-defined tasks, would validate the value

proposition and likely accelerate commercialization.

- *Scaling and reliability milestones*: Since long-term viability depends on scaling up quantum hardware, indicators like demonstrated error-corrected operations (logical qubits with lower error rates)[12][13], increases in qubit counts, and stable cloud uptime of quantum processors are important. Achieving error rates low enough for deep circuits or demonstrating modular quantum systems that can expand (as in IBM’s quantum-centric roadmap) shows the approach is approaching technical readiness for wider deployment.

## 2. Evidence (10–20 recent, reliable sources)

3. **IBM (Jay Gambetta) – “Quantum-centric supercomputing: The next wave of computing” (IBM Quantum Blog, Nov 2022)**: IBM’s 2022 Quantum Summit declared **2023 as an inflection point** toward “quantum-centric supercomputers” – modular architectures that tightly integrate quantum processors with classical HPC through a cloud middleware[14]. IBM’s roadmap describes enabling seamless quantum-classical workflows (using tools like Qiskit Runtime and “Quantum Serverless”) so that quantum accelerators can function like GPU-style co-processors in AI applications[15][16]. This shows a major industry player actively engineering the software/hardware stack for hybrid quantum–AI computing.
4. **Z. Yin et al. – *Nature Photonics* 19, 1020 (June 2025)**: Demonstrated **quantum-enhanced machine learning** on a photonic processor for a real classification task[7]. Using single-photon interference (no entangling gates), their quantum kernel method outperformed state-of-the-art classical kernel techniques (Gaussian and neural tangent kernels) on a binary classification benchmark[7]. This peer-reviewed experiment provides concrete evidence that current quantum devices, in at least certain domains, can achieve higher accuracy than classical methods, highlighting the plausibility of performance gains in AI tasks.
5. **A. Gircha et al. – *Scientific Reports* 13:8250 (May 2023)**: Presented a **hybrid quantum–classical generative model** for drug discovery, training a discrete variational autoencoder where a quantum Restricted Boltzmann Machine (RBM) served as the latent layer[6]. The RBM was small enough to run on a D-Wave quantum annealer, which was used to sample latent variables while a classical neural network handled the rest. They successfully trained this model on a chemical dataset (ChEMBL) and generated novel molecular structures[6]. This illustrates a practical prototype using an existing quantum annealer to enhance an AI model, and demonstrates feasibility on presently available quantum hardware (NISQ annealers) for real-world data.
6. **M. Slys et al. – “Hybrid Classical-Quantum Supercomputing” (Preprint, Aug 2025)**: Researchers from Poznan Supercomputing Center (Poland), NVIDIA, and ORCA Computing built the **world’s first multi-user hybrid quantum-HPC cluster**[3]. In this setup, photonic quantum processors (by ORCA) are installed alongside GPUs in a conventional data center, with standard HPC scheduling (Slurm) and NVIDIA’s CUDA-Q software coordinating the quantum/classical workload[3][4]. They demonstrated variational quantum algorithms for machine learning and optimization running on this cluster, showing that *multiple users can share quantum accelerators just like HPC resources*. This is strong evidence of system-level maturity: quantum accelerators can be practically integrated into modern computing centers without exotic infrastructure changes, paving the way for real-world trials.
7. **Oak Ridge National Lab – “ORNL, NVIDIA, HPE advance Quantum Computing, AI, and HPC” (Lab news, Nov 2025)**: DOE’s Oak Ridge Lab announced a partnership with NVIDIA and HPE to develop a **testbed integrating quantum processors with the Frontier exascale supercomputer**[17][9]. They are using NVIDIA’s “NVQLink” and CUDA-Q to link quantum hardware with GPUs/CPUs, aiming to explore quantum acceleration for scientific AI

workloads[9]. The platform, arriving in 2026, will support error-correcting control and hybrid algorithms in one environment. This high-profile investment – effectively building a quantum-augmented supercomputer – underscores that multiple major players see hybrid quantum–AI computing as within reach.

8. **Forschungszentrum Jülich – Integration of 100-qubit quantum system (Germany, 2025):** The Jülich Supercomputing Centre (JSC) expanded its infrastructure (JUNIQ) by adding “**JADE,**” a **100-qubit Pasqal quantum computer, integrated with its new exascale system (JUPITER)**[18]. Inaugurated in 2025, this setup allows researchers to experiment with hybrid HPC-quantum applications for optimization and materials science[18][19]. JSC’s directors emphasize that quantum computing at Jülich is “*not a separate track*” but complements classical HPC, with quantum resources situated alongside supercomputers for a continuum of computing paradigms[19]. This evidences a major European effort to operationalize quantum accelerators in AI and simulation workflows and reflects a broader trend (EuroHPC JU program) of installing quantum nodes at supercomputing centers across Europe.
9. **D-Wave Systems – Press Release: Feature Selection Hybrid Solver (Mar 2023):** D-Wave (a commercial quantum computing company) released a **hybrid quantum feature selection plugin** for machine learning, highlighting concrete enterprise-focused tooling[8][5]. The plugin integrates with the popular scikit-learn ML library, letting developers use D-Wave’s quantum-classical solver to automatically pick influential features in datasets[5]. By abstracting the complex optimization behind a familiar interface, this product shows a push toward real-world AI workflow integration. Its launch – and reports that customers find quantum hybrid solutions beneficial for speeding up model training[20] – signals that quantum acceleration is moving into practical AI software (at least in niche optimization tasks) with commercial support.
10. **A. Shehata et al. – Future Generation Computer Systems 174, 107980 (Jan 2026):** This paper from ORNL outlines a **comprehensive software stack for HPC-Quantum convergence**[1], addressing many technical challenges of hybrid workloads. It proposes hardware-agnostic interfaces for resource management, a quantum platform manager API to plug in different QPUs, and unified scheduling to handle interwoven quantum and classical tasks[1][21]. They implemented test algorithms (e.g. a variational quantum linear solver) to show the framework managing complex workflows and maximizing resource use[2]. The work, funded by the US DOE, serves as a blueprint for future quantum-accelerated HPC systems. Its existence indicates that the community is not just theorizing but actively building the *middleware and tools* needed to deploy quantum accelerators at scale in AI and scientific computing environments.
11. **M. Sciorilli et al. – Nature Communications 16:476 (Jan 2025):** Achieved a breakthrough in **qubit-efficient quantum optimization**. They introduced a variational algorithm that solved a MaxCut graph problem with  $m = 2000$  variables using only 17 trapped-ion qubits[22][11]. In experiments, the quantum solver reached a graph cut solution quality above the known classical hardness threshold (approximation ratio  $>0.941$ ) for that problem size[11]. This result is noteworthy because it suggests a route to tackle industrial-scale combinatorial problems on today’s small quantum devices by clever encoding and hybrid processing. It provides evidence that even before full fault-tolerance, carefully designed quantum accelerators could offer an **optimization advantage** on relevant AI problems (like network design, scheduling, etc.), underscoring the plausibility of value creation in the near term.
12. **Google Quantum AI – Nature 614, 676 (Feb 2023):** Demonstrated the **scaling of quantum error correction**, a crucial stepping-stone for quantum-assisted AI. Google’s team showed that on a 72-qubit superconducting chip, a larger distance-5 surface code (49 physical qubits per logical qubit) achieved a lower error rate per cycle than a smaller distance-3 code (17

qubits)[12]. This marked *the first experimental proof* that adding qubits and complexity can actually suppress errors (the logical error rate ~2.9% vs 3.0%)[12][13]. Reaching this “break-even” and beyond is essential for scaling quantum processors to the sizes needed for AI applications. This achievement, with logical qubits now outperforming uncorrected ones, indicates rapid progress in hardware maturity – it builds confidence that fault-tolerant quantum operations (needed for long or complex AI computations) are on the horizon.

### 13. Maturity score (1–7) and reasoning

**Overall Maturity Score: 5** (out of 7) – *Active R&D with multiple competing prototypes; clear progress post-proof-of-concept, but not yet broadly deployed or proven superior to classical systems in practice.*

**A. Justification of score:** Quantum-accelerated AI systems have moved beyond theory (levels 1–2) and isolated lab demos (level 3) into an intense prototype development phase. We have **credible proof-of-concepts**: e.g. a photonic quantum ML classifier beating classical kernels[7] and hybrid quantum models generating drug-like molecules[6], which **rules out the lower levels** by demonstrating core functionality. Moreover, full prototypes are being assembled in real computing environments – such as the multi-user quantum-HPC cluster in Poznan[3] and quantum-enhanced supercomputing initiatives at IBM and ORNL – indicating that the technology is approaching the level 4 threshold (functional PoC with viability for production). The reason we assign **level 5** is the breadth of well-funded actors now in the race: **major companies, national labs, and startups are investing heavily and even collaborating to build next-stage systems**[17][9]. There are multiple efforts to integrate quantum accelerators into standard workflows (IBM’s Quantum Network with 200+ members, Amazon/Azure quantum cloud services, European HPC centers hosting quantum hardware), which is characteristic of level 5 where competition and development of production prototypes heat up.

Crucially, what **keeps the score at 5 and not 6** is that we have yet to see *routine delivery of this technology to end-users with scaling-up in production*. While D-Wave does offer a commercial quantum service (and even a feature-selection tool[8][5]), and IBM gives cloud access to prototype quantum processors, these are still specialized or pilot services – not widely adopted products solving mainstream AI problems. No clear quantum advantage has been demonstrated on a real-world scale problem that outperforms classical HPC (the **next milestone** needed to justify level 6). Error rates and qubit counts, though improving (with milestones like Google’s error-corrected qubit[12][13]), remain limiting factors that prevent general deployment. In summary, the field has advanced past proof-of-concept into an innovation race (score 5), but **to reach level 6**, we would expect to see **early market offerings being delivered at scale** – for example, turnkey quantum-accelerated AI services with growing enterprise adoption, falling costs, and multiple vendors’ systems in practical use. Those conditions are not yet met.

**B. Sub-component analysis:** The composite score of 5 is an aggregate view, as this ART spans several elements at different maturity:

- *Quantum hardware*: Present quantum processors (superconducting qubits, ion traps, etc.) are roughly at **level 3–4** – laboratory prototypes showing key functionality (entanglement, basic algorithms) and even some narrow advantage, but still needing improvements in error correction and scale. For instance, a 17-qubit system solving a 2000-variable optimization is impressive[11], yet quantum hardware must grow orders of magnitude to tackle general AI

tasks. Recent error-corrected qubit demonstrations (Google, 2023) indicate hardware is advancing steadily toward the threshold of practical reliability[12][13].

- *Hybrid algorithms and software*: Integration frameworks and algorithms are nearer **level 4–5**. We see robust prototypes of middleware (e.g. ORNL’s software stack for quantum-HPC integration[1][2]) and established APIs (Qiskit, Cirq, PennyLane) that allow developers to embed quantum routines into AI code. Many variational and hybrid algorithms have been tested on real devices, showing feasibility in principle. The **viability for production** is being proven by efforts like D-Wave’s hybrid cloud solvers and IBM’s runtime, which focus on user-friendly incorporation of quantum in standard workflows – a sign of approaching commercial readiness.

- *Use-case performance*: For the intended value (accelerating AI), the evidence is still emerging. In niche cases (certain optimizations or kernel methods) we have seen **quantum-enhanced performance (level 4)**, but broadly speaking classical AI is not yet outclassed. The **benefit is divided across sub-areas** – e.g. quantum annealing might help discrete optimizations, while gate-model circuits explore deep learning enhancements. Since all variants aim at the same ultimate functionality (faster or better AI outcomes), we lean toward the higher end of their maturity spectrum in scoring.

Considering these aspects together, we averaged the maturity signals and also noted the **concerted push by multiple stakeholders (hallmark of level 5)**. Thus, **score 5 represents the overall bundle**. The score reflects that the concept is **beyond proof-of-concept and firmly in development/optimization**, with prototypes in integration testbeds and early adopter usage, but still awaiting the breakthrough that would trigger broad deployment and competition in end-user markets (which would correspond to level 6).

## ART 03.021 AI-Driven Autonomous Scientific Discovery

### 127. **ART extraction**

128. *Primary capability:* AI-driven systems that autonomously conduct much of the scientific discovery process – from generating hypotheses and designing experiments to executing those experiments and interpreting results, all with minimal human intervention. These “AI scientists” act as continuously learning research engines, able to propose research questions and workflows and refine their approach based on data, while remaining transparent and steerable by human experts.

### 129. *Key sub-components/variants:*

- **Large-scale AI models + scientific knowledge bases:** Combining powerful machine learning (e.g. large language models) with structured domain knowledge to reason about hypotheses and experimental design[1][2].
- **Automated experimentation platforms:** High-throughput robotic labs (chemistry, materials, biology, etc.) that can be programmatically controlled to run experiments or simulations, with real-time data collection[3][4].
- **Closed-loop decision systems:** AI agents that iteratively plan experiments, analyze outcomes, then propose the next experiments (active learning), enabling autonomous optimization or discovery without exhaustive human scripting[5][6].

- **Natural language and high-level interfaces:** Interactive front-ends (LLMs, dashboards) allowing humans to set goals or constraints in plain language, which the AI translates into experimental actions[1][7].
- **Safety and verification layers:** Mechanisms to validate experiment proposals and ensure safe, valid operations (e.g. filtering out nonsensical or dangerous actions before execution)[8].

130. **Maturity indicators (evidence of plausibility & progress):** Key signs would include **lab prototypes** demonstrating autonomous research loops (e.g. AI-driven systems discovering new materials, chemicals, or scientific insights)[9][10]. **Proof-of-concept (PoC)** milestones might be an AI-driven lab outperforming or accelerating human-led research (e.g. finding better solutions faster or at lower cost[11]). We'd expect **field trials or real-world deployments**, such as closed-loop AI labs in active use at research institutions or companies[12][13]. **Commercial or scaling signals** could include industry partnerships (lab automation companies integrating AI[14][15]), **well-funded initiatives** (government or corporate programs investing in AI-discovery platforms[16][17]), and early **products or services** (e.g. cloud-based "AI lab" services, or AI-optimized reagents entering the market[13][18]).

131. **Evidence (10–20 recent, reliable sources)**

**1. Autonomous Materials Synthesis Lab – Szymanski et al., Nature (Nov 2023):** Peer-reviewed article. Demonstrates a robotic "self-driving" lab (A-Lab) that planned and executed 57 solid-state inorganic syntheses with minimal human input, successfully producing 36 target compounds in 17 days of continuous operation[5][19]. The AI used ab initio databases and text-mined literature to generate experimental recipes, which were carried out by robots, achieving a high success rate and showcasing closed-loop discovery in materials science (significantly accelerating experimental throughput)[9]. This validates the *feasibility* of autonomous discovery in chemistry and materials.

**2. GPT-4 "Coscientist" for Autonomous Chemistry – Boiko et al., Nature (Dec 2023):** Peer-reviewed article. Reports an AI agent ("Coscientist") driven by GPT-4 that autonomously **designs, plans, and performs complex chemistry experiments** end-to-end[2]. It integrated tools like internet/library search, code execution, and control of cloud laboratory instruments. In six diverse experimental tasks (e.g. optimizing a palladium-catalyzed reaction), the system not only devised and ran experiments but matched human scientists in decision quality[20]. This illustrates plausible autonomy: LLM-based agents can coordinate real lab hardware via natural language and achieve tangible research outcomes[21][12].

**3. AI-Driven Battery Electrolyte Discovery – Noh et al., Nature Communications (Mar 2024):** Peer-reviewed article. Describes a high-throughput robotics platform combined with an active-learning AI to discover improved redox flow battery electrolytes[22]. Starting from >2000 possible solvent mixtures, the AI-guided loop tested <10% of them yet found formulations dissolving **3× more** active material (over 6.2 M concentration) than prior state-of-the-art[23]. This efficient search – narrowing the "haystack" to the best candidates[24][25] – highlights how autonomous experimentation can **vastly accelerate discovery** (540+ solvents characterized in months[26]) and achieve performance beyond what human trial-and-error would likely obtain[27][28].

**4. GPT-5 Autonomous Bioexperiment Loop – Ginkgo Bioworks & OpenAI (preprint, Jan 2026):** Preprint (press release, industry R&D). Ginkgo Bioworks (biotech company) and OpenAI built a closed-loop AI "**robot scientist**" for biochemistry that ran **36,000 experiments over 6 months** with minimal human input[29][30]. The system, powered by a

next-gen GPT-5 model, iteratively designed and executed experiments to optimize a cell-free protein synthesis process, **reducing cost per protein by ~40%** vs. previous best[29][31]. Notably, the AI autonomously proposed new reagent combinations (some later confirmed independently in literature)[32], and the improved reaction mix it developed is now being *sold commercially* as a reagent[13][18]. This is a strong proof-of-concept that AI-driven discovery can yield **practical, marketable innovations**, signaling maturity beyond academia.

**5. AI Agent for Quantum Lab Experiments – Cao et al., *Patterns (Cell Press)* (Oct 2025):** *Peer-reviewed article*. Introduces a “**k-agents**” framework using LLM-based agents to automate *entire* experimental procedures in a quantum computing lab[33]. The AI agents encapsulated lab knowledge and split complex protocols into sub-tasks, enabling **multi-hour autonomous operation** of a superconducting quantum processor[34]. In tests, the system **achieved expert-level performance** – autonomously calibrating qubits and producing entangled quantum states as well as human scientists[35][36]. This demonstrates the *generality* of autonomous discovery: even in cutting-edge physics experiments, AI agents can run experiments and interpret outcomes on par with trained researchers, underscoring the approach’s broad feasibility.

**6. “AI Scientist” for ML Research – Lu et al., *arXiv preprint (Aug 2024):*** *Technical preprint (Oxford/UBC collaboration)*. Describes an *open-ended* AI research system (“The AI Scientist”) that automates the full scientific cycle in the domain of machine learning research[37][38]. Starting from a prompt, the system generates novel hypotheses/algorithms, writes code, runs experiments (training models), and writes up findings as a publishable paper – even performing an automated peer review of its own drafts[39][40]. In a first demonstration, it independently produced new ideas in areas like transformers and diffusion models, each idea developed into a paper at an estimated cost of only ~\$15 in compute[41]. While domain-limited (software experiments), this showcases a plausible future variant: *AI autonomously conducting theoretical or computational research*, indicating how far the automation could go when provided a suitable sandbox.

**7. Enhancing Novel Discovery (not just Optimization) – Bulanadi et al., *ACS Nanoscience Au* (Oct 2025):** *Peer-reviewed article*. Focuses on pushing autonomous scientific agents beyond just optimizing known targets, toward **finding truly new phenomena**. Proposes an “INS<sup>2</sup>ANE” strategy combining a novelty score and strategic exploration to have AI-driven experiments seek out unusual results[42][43]. Implemented on an autonomous microscope system at Oak Ridge NL, this approach led to significantly **greater diversity of discoveries** compared to standard optimization, revealing previously unobserved behaviors in materials imaging[44][45]. This indicates a maturation of the field: researchers are now tackling how AI scientists can surprise us with *unexpected insights*, not just reproduce human-guided goals, which is key to fulfilling the full promise of autonomous discovery.

**8. National “Self-Driving Labs” Roadmap – DOE Workshop Report (Nov 2024):** *National lab consortium report*. Summarizes a U.S. Department of Energy workshop on scaling **self-driving laboratories** across domains[46][47]. It highlights critical needs like standardized data management, AI decision-making frameworks, and integration of robotic instruments at national user facilities[48][47]. The report emphasizes that autonomy will require fusing machine learning with human domain knowledge and careful safety/ethics review, and calls for building a “**Labs of the Future**” **consortium**[49][50]. This shows that major research

stakeholders are actively planning the **infrastructure and policies** for AI-driven discovery, a sign of preparation for broader deployment.

**9. Thermo Fisher & NVIDIA Partner on AI Lab Tools – *Thermo Fisher press release (Jan 2026): Vendor technical announcement.*** Thermo Fisher Scientific (a top lab equipment maker) announced a strategic collaboration with NVIDIA to embed AI capabilities into lab instruments and software at scale[51][52]. The goal is “lab-in-the-loop” experimentation where AI agents assist in experiment design, real-time data analysis, and instrument control during runs[53][54]. For example, their new Attune CytPix flow cytometer uses on-board AI to analyze cell images and guide experiments in real time[55][56]. This industry move shows that **commercial lab platforms are adopting AI autonomy features**, indicating a push toward products that can automate research workflows and *deliver them to end users*.

**10. U.S. DOE “Genesis” Mission for AI-Accelerated Science – *White House Executive Order (Nov 2025): Authoritative government roadmap.*** The Genesis Mission is a national initiative to create an integrated platform linking supercomputers, AI models, and robotic labs to **enable autonomous scientific discovery at scale**[17][57]. It explicitly calls for developing AI agents that can explore hypothesis spaces, automate experiments, and iterate in closed-loop fashion across scientific disciplines[58][59]. This high-level commitment (likened to a Manhattan Project for AI-driven science[60]) reflects both the plausibility and strategic importance seen in this technology: multiple federal labs and major institutions are now funded to realize **AI-run experiments** and shorten discovery cycles, aiming to keep national R&D at the cutting edge[16].

#### 132. **Maturity score (1–7) and reasoning**

**A) Score – 5 (out of 7).**

**B) Reasoning –** The evidence indicates that *AI-driven autonomous discovery* is **well beyond the early theoretical or single-lab prototype stage**, and is now entering an intense development and scaling phase. **Level 3 (lab prototype)** is clearly surpassed: we have multiple working prototypes across domains (chemistry, materials, biology, even quantum physics) showing that key technical hurdles can be solved – e.g. an autonomous materials lab ran 57 syntheses continuously[5], and an AI planned multi-step chemistry experiments with human-level skill[2]. These successes also meet **Level 4 (Proof-of-Concept)** criteria: the autonomous systems demonstrated *clear benefits over traditional approaches*, such as discovering a cheaper process than any human had (40% cost reduction in protein production)[31], or finding battery solvents that far exceeded prior solubility limits[61]. This shows that AI labs can not only function, but *outperform classical R&D baselines*, satisfying the “exceeds previous solutions in benefit” condition for level 4.

We assign **Level 5** because multiple well-funded actors are now pushing toward **production-ready platforms**. Evidence of this “race” includes the partnership of a major lab vendor and an AI chipmaker to build **autonomous lab products** (Thermo Fisher + NVIDIA, 2026)[54], the involvement of big tech (OpenAI, Google DeepMind) with biotech and national labs in this domain[62][63], and the launch of large-scale programs like DOE’s Genesis Mission to unify resources for AI-driven science[17][59]. There is a clear *commercial and strategic momentum*: companies are beginning to **deliver early offerings** (e.g. cloud labs with AI copilot functionality[12], AI-optimized reagents on sale[13], smart instruments like Attune CytPix shipping to labs[55]), and significant investments are flowing (national labs

consortium, new startups, etc.). All this suggests the field is moving fast *post-PoC*, aiming to deploy robust systems in real research environments – exactly the essence of level 5.

Lower maturity levels are ruled out by the breadth and recent pace of progress. Unlike level 2, we now have repeated experimental validation, not just isolated lab tests. And unlike level 3–4, development is not confined to one-off demos; **concurrent efforts** are tackling scaling, usability (natural language interfaces[64]), and integration into existing R&D infrastructure[65][66]. The concept is no longer speculative: it’s actively being engineered into products and national R&D strategies.

We do *not* yet score it a 6, because fully mature **products aren’t widely delivered at scale**. There is not yet a turnkey “AI Scientist” in routine use across industry – current deployments are mostly pilots or specialized use-cases. To reach level 6, we’d expect to see many labs routinely buying or subscribing to autonomous discovery systems, with costs dropping and production volumes rising. That level of market penetration and competition (analogous to, say, widespread use of DNA sequencers or cloud computing in labs) is still forthcoming. Key evidence missing for level 6–7 is broad customer adoption and multiple competing products with significant revenue. We see *early signs* (e.g. Thermo’s initiative, Emerald Cloud Lab’s expansion[67]), but the *ecosystem* of competing, mature products is just beginning to form. In short, **autonomous scientific discovery is in the advanced development/prototyping phase (Score 5)**: proven viable with strong advantages, backed by multiple major players, and now on the cusp of initial real-world rollout – but not yet a ubiquitous commodity in the research marketplace.

**C) Sub-component breakdown:** This ART blends several technologies, each at slightly different maturity, but converging toward an integrated capability:

- *Robotic lab automation hardware*: Fairly mature (many labs already use automated equipment; some cloud lab services exist). **Maturity ~6**, as robots and instruments are delivered and used routinely – however, these operate mostly under human programming rather than full AI autonomy[68][66].
- *AI planning and reasoning software*: Rapidly evolving. LLM-based experiment planners only emerged in the last 1–2 years[2]. They have achieved **proof-of-concept (4)** by executing real experiments, even matching human expert decisions[69][34]. But reliability, safety, and generality are still being improved, and this software isn’t yet a shrink-wrapped product.
- *Integrated autonomous research systems*: The full stack (AI + lab hardware + data systems) is currently at **PoC to pilot stage (4–5)**. Some integrated prototypes have met important benchmarks (e.g. discovering new materials/drugs faster or cheaper) and even delivered an early commercial outcome (new reagent)[18]. Multiple actors are now building on these prototypes (indicating a move into level 5). Overall functionality is similar across variants (all aim to automate the research loop), so the most advanced instances push the composite maturity upward. We therefore weigh the **maximum** demonstrated capability – level 5 – as representative of the bundle’s state. The robustness of the hardware and the clear PoCs achieved justify at least level 4, and the multi-actor push justifies elevating to 5.

In summary, **we score this ART as a 5**, reflecting a technology on the brink of practical deployment. The concept is validated and highly promising (no fundamental science barriers remain – it works), and the race is on to polish and scale it. However, the step to level 6 will require these autonomous discovery systems to transition from pilot projects to widely

adopted research tools, a step likely to unfold in the coming few years. The evidence to date rules out any lower rating, but also underscores the gap to full commercial ubiquity.

---

## Group 4 – Human-Machine Interaction & Augmentation

### ART 04.022 Immersive Augmented & Virtual Reality

#### 133. ART extraction

134. *Primary capability:* Integrating **digital content seamlessly with the physical world** via head-worn displays that render immersive augmented, virtual, or mixed reality (XR). This enables virtual objects and information to appear **co-present and spatially anchored** in a user's real environment, or to fully simulate immersive virtual environments.

#### 135. Key sub-components/variants:

- **Augmented Reality (AR) glasses:** Lightweight, transparent smart glasses for everyday use, overlaying graphics onto real-world view. Emphasis on **compact optics** (waveguides, holographic combiners) for wide field-of-view see-through displays, and on all-day comfort (weight, thermal)[1][2].

- **Virtual/Mixed Reality (VR/MR) headsets:** Enclosed or passthrough-view headsets (e.g. VR headsets with high-resolution displays and MR color cameras) for **full immersion**. Prioritize wide FoV, spatial audio, and precise inside-out tracking of environment and user (head, hands, eyes)[3][4]. Often tetherless but heavier, with shorter battery life[5]. Room-scale installations (CAVEs, simulators) offer shared immersion at larger scale.
  - **Spatial mapping & sensors:** Onboard **cameras, depth sensors (LiDAR)** and IMUs to continuously scan surroundings, reconstruct surfaces, and track user position and motions in 3D[3]. **Eye-tracking** cameras and **hand-tracking** (via vision or controllers) enable natural input and foveated rendering[3][4]. Optional body or face tracking can be added for avatars.
  - **User interaction & feedback:** Multimodal inputs – **voice commands, gaze targeting, gesture recognition**, and handheld controllers – provide intuitive control[4]. **Spatial audio** (3D sound) is standard, and **haptic feedback** (e.g. vibrations in controllers, gloves or suits) is sometimes integrated to enhance realism.
  - **Software & content:** Common **XR software platforms (e.g. OpenXR, ARCore/ARKit)** allow developers to extend existing 2D apps into 3D space or build new immersive experiences[6][7]. The system anchors virtual content to real-world **coordinates or surfaces** (persistent AR anchors[8][9]), enabling multi-user shared experiences. **On-device or cloud AI** may personalize the experience by learning user preferences, context, and intent (e.g. adaptive interfaces or intelligent assistants that provide just-in-time guidance)[10][11].
136. **Maturity indicators:** Evidence would include **functioning prototypes and commercial products** (e.g. AR headsets like HoloLens 2, Magic Leap 2; VR headsets like Meta Quest, Sony VR, Apple Vision Pro), with **field trials or deployments** (enterprise or military use, developer kits)[12][13]. Key indicators are **increasing unit shipments**[14], multiple large **companies investing and competing** (Apple, Microsoft, Meta, Google, Sony, etc.), **standards and ecosystems** (OpenXR adoption, content libraries)[6][15], and demonstrated **performance milestones**: e.g. achieving wide FOV, high resolution displays[1][16], accurate tracking, and improvements in battery life or form factor. Also evidence of **value in practice** – studies or trials showing XR reduces task errors, training time, or other bottlenecks – would support plausibility[17][18].
137. **Evidence (10–20 recent, reliable sources)**
138. **Holographic Waveguide AR Display Prototype – Jang et al., Nature Communications (2024):** Researchers demonstrate a **compact near-eye display** combining waveguide combiners with true 3D holographic projection. The prototype achieved a >10° diagonal field-of-view with a software-steerable large eyebox, addressing challenges of **vergence–accommodation conflict and image quality** in AR glasses[19][20]. *This peer-reviewed experiment shows progress toward high-resolution, comfortable AR eyewear, using novel optics to overcome focus depth and compactness limitations.*
139. **Meta-Analysis on AR/MR Training Efficacy – Liu et al. (Macao Polytech/U. Macao), BMC Med. Educ. (Accepted 2025):** Analyzes 29 studies of AR/MR in medical education. **Hands-on skill training improved significantly** with AR/MR: on average ~12.3-point higher skill scores, ~8% lower failure rates, and faster task performance than traditional methods[21]. No major gains in textbook knowledge, but **user acceptance was higher** (e.g. higher perceived usefulness and enjoyment)[22][23]. *Demonstrates that AR/MR can tangibly enhance complex*

*procedural training, supporting the technology's value in reducing errors and cognitive load for real-world tasks.*

140.     **Augmented Reality Assembly Guidance – Osman et al., Int. J. Informatics Visualization (2020, study continued into 2022):** In a controlled trial for PC assembly, an **AR headset overlay** led to **significantly fewer errors and faster assembly times** compared to paper instructions[17]. Users with AR completed tasks with improved accuracy and speed, confirming that **just-in-time 3D guidance** can alleviate misinterpretation and reduce task completion time vs. traditional manuals[24][17]. *This illustrates XR's potential to offload cognitive effort in complex layout understanding and procedural work.*
141.     **US Army IVAS Field Trials (HoloLens-based) – Army Times (Dec 2023):** The Army has procured **10,000+ AR combat headsets** (Integrated Visual Augmentation System) based on Microsoft HoloLens tech for testing and training[12]. Early versions (IVAS 1.0/1.1) were delivered in 2022–23, and an improved 1.2 prototype (20 units) began troop trials in 2023 with ~280 more sets planned by 2025 for broader fielding[12][13]. These see-through headsets integrate **night vision, thermal imaging, and tactical data**: soldiers can view weapon-sight video feeds in their HUD, see digital waypoints/enemy markers overlaid on terrain, and even control micro-drones with live AR map updates[25][26]. *This indicates a well-funded, at-scale prototype deployment addressing situational awareness bottlenecks; it also reveals current challenges (field of view, soldier comfort) being iteratively solved in a high-stakes environment.*
142.     **Global AR/VR Headset Shipments – IDC Worldwide Quarterly Tracker (IDC press release, Mar 2023):** Reports that **2022 saw ~8.8–9.7 million AR/VR headsets shipped** (slight dip in growth), and **2023 shipments were forecast ~10.1 million** (14% YoY growth)[14]. Consumer VR remains the dominant segment (gaming and entertainment driving volume), but IDC notes **increasing investment in consumer AR glasses** by brands like Xiaomi, Oppo, TCL, etc., alongside major VR device launches from Sony (PSVR2), Meta, Apple, and Pico[27][28]. *This underscores that multiple well-capitalized industry players across the US, Asia, and Europe are delivering XR hardware to a growing market (tens of millions of units annually), reflecting improving technology and expanding interest.*
143.     **Google “Android XR” Platform Launch – S. Izadi (Google VP), Google Blog (Dec 2024):** Google announced **Android XR**, a new OS for AR/VR devices made with Samsung & Qualcomm, signaling a unified ecosystem for upcoming headsets and glasses[6]. The developer preview supports standard XR frameworks (**ARCore, OpenXR, Unity**) so existing mobile apps and data can **seamlessly extend into 3D space** (e.g. YouTube, Maps, Chrome running as floating AR windows)[7]. It integrates Google’s **“Gemini” AI assistant** that can see and understand the user’s environment and context – users can interact conversationally about what’s in view or get guided through tasks in AR[10]. Google also emphasized plans for **all-day AR glasses** that are as lightweight as normal eyewear, tightly integrating with smartphones and cloud services[29][11]. *This highlights significant software infrastructure maturity: tech giants are actively prepping for mass XR adoption by enabling cross-device app compatibility, AI-driven context awareness, and a pipeline of devices from multiple manufacturers.*
144.     **Apple Vision Pro Technical Documentation – Apple (June 2023):** Apple’s “spatial computer” (Vision Pro) showcases the state-of-the-art: it features dual **micro-OLED displays with 23 million pixels total** (approaching retinal resolution) for an immersive MR visual experience[30]. The headset is studded with **12 cameras and 5 sensors**, including **two color pass-through cameras, six IR tracking cameras, four eye-tracking cameras, a LiDAR depth scanner**, plus IR projectors for precise hand and eye tracking[3]. It supports **natural hands-free input** (tracked hands, eye-gaze dwelling, and voice commands) as primary interaction[4].

**Spatial audio** is delivered via integrated speakers and beamforming mics[31]. A dedicated R1 chip processes sensor data in 12 ms for responsive mixed reality. *Notably, the Vision Pro's battery life is ~2.5 hours on a wearable pack[5], illustrating the power/thermal constraints of this compact form-factor, despite Apple's advanced silicon.* Overall, this **commercial product** exemplifies the high-end of XR capabilities (ultra-high resolution, precise environment capture, intuitive UI), while highlighting ongoing limits in **wearability (~800 g headset) and endurance[32][5]**.

145. **Magic Leap 2 AR Headset – Product Spec (Magic Leap, v1.2, 2022):** The Magic Leap 2 (enterprise-focused AR glasses) introduced **proprietary optics that doubled the field-of-view** (~70° diagonal, up from ~50°) while maintaining a see-through display[2]. It also added **Dynamic Dimming™** – an electrochromic layer that can electronically dim the lenses up to 99.7%, improving contrast of AR imagery even in bright environments[33][2]. To achieve all-day wearability, ML2 offloads processing and power to a hip-mounted “Compute Pack,” making the **headset ~50% smaller and 20% lighter** than the prior model[34]. It features one of the highest compute specs in AR (custom AMD SoC) with **2–3× performance boost**, and includes **advanced sensors** (eye tracking, hand tracking, spatial mapping cameras) plus **iris-scanning biometrics** for secure logins[35][36]. The device runs an open **Android-based OS** to ease custom app development and IT integration[37]. *This represents a refined production prototype of AR glasses: significantly improved visual and ergonomic performance over earlier generations, albeit at high cost (~\$3,000) and still tethered. It underscores progress in optical engineering and the emphasis on enterprise use (with data privacy controls for on-premises/cloud and multi-user management)[38].*
146. **Persistent Multi-User AR Content – Google ARCore Cloud Anchors (Dev Documentation, updated Nov 2025):** Google's Cloud Anchor API allows AR applications to **host virtual anchors in the cloud that persist over time and across devices[8]**. For example, a user can pin a virtual object or note to a real-world location (like a machine in a factory or a spot on a remote site) and other users, even on different platforms (Android or iOS), can later see that same AR content precisely overlaid in the same place[8][9]. **Shared AR experiences** are enabled by exchanging a Cloud Anchor ID, letting multiple people collaborate in real time (e.g. two users see and manipulate the same virtual object on a table from their own devices)[39][40]. *This cloud-backend capability demonstrates that the ecosystem has evolved to support persistent, networked spatial content, which is crucial for real-world deployment of AR in maintenance, remote assistance, and collaborative design – addressing the bottleneck of content calibration and multi-user consistency.*
147. **Next-Gen AR Display Tech – TriLite CTO J. Reitterer interview, Markt & Technik/TriLite News (Dec 2023):** Industry experts acknowledge that **optical display quality remains a key constraint** for consumer AR. For instance, **microLED micro-displays**, once expected to enable compact AR glasses, are “*still too expensive, not bright enough, and don't provide sufficient resolution*” at scale – even Apple's flagship device opted for microOLED instead[1]. In response, companies are pursuing alternatives like **Laser Beam Scanning (LBS)** projectors, which use MEMS mirrors and laser diodes. LBS engines can be extremely small and lightweight while delivering very bright images; importantly, “*LBS is the only available tech that maintains size/weight while increasing field-of-view and resolution*”[16]. TriLite and partners (TDK, ams Osram, Dispelix, etc.) in 2023 demonstrated a postage-stamp-sized LBS projector (Trixel 3) that won awards for enabling true eyeglasses-like AR form factors. *This evidence highlights active R&D in overcoming optical and manufacturing bottlenecks: a push toward mass-producible, wide-FOV displays for AR that could finally achieve the cost, brightness, and slim form factor needed for broad consumer adoption[41][1].*
148. **Maturity score (1–7) and reasoning**

## Proposed Maturity Score: 6 (Advanced prototypes and initial products, nearing scale-up)

**A) Justification for score:** The immersive AR/VR technology bundle has moved well beyond lab demos – it now features **commercial products in the hands of users** and **multiple competing major players**, which rules out Levels 1–4. VR headsets especially are a maturing market: millions of units ship yearly and are iteratively improving[14][27], satisfying Level 6 criteria (“products delivered to customers in increasing amounts; application areas expanding”). High-end MR devices like the Apple Vision Pro are launching as polished products (albeit expensive), demonstrating full functionality (rich visuals, intuitive interaction) that clearly **exceed prior solutions** like flat screens in immersion and capability[3][4]. The evidence also shows **fast-paced progress and heavy investment**: e.g. Google’s and Meta’s platforms, Apple’s device, and others all advancing in parallel[6][27]. This competitive ecosystem with well-funded actors pushing toward scalable production (Apple’s supply chain, Qualcomm reference designs, etc.) is characteristic of Level 6.

Level 5 (post-Proof-of-Concept prototypes) is too low given that **multiple products are already deployed** outside the lab. For instance, **enterprise and defense AR systems are in field trials and limited deployment** (thousands of IVAS headsets contracted by the US Army)[12][13], and companies like Magic Leap are on their second-generation AR device being sold to industry[2][34]. Such traction indicates we are past one-off prototypes – the technology works well enough to attract early customers and iterative refinement, which aligns with Level 6.

We do not yet assign Level 7 because **mass-market adoption and sustainable commercial traction are still emerging**. While there are competing products on the market (Meta vs. Apple vs. Pico in VR, etc.), the overall XR sector has not yet proven “*rising demand*” from a wide consumer base or achieved economies of scale to sharply lower prices (in fact, AR glasses remain expensive). *What’s still missing for Level 7:* We need to see **broader consumer uptake of AR devices** (beyond enterprise and enthusiasts) – for example, truly wearable AR glasses at affordable prices – and multiple firms profitably scaling up production for a **wide clientele**. Current evidence shows technical viability and early-market penetration, but not yet the *ubiquity* or cost reduction that Level 7 implies. Moreover, some critical bottlenecks (display brightness, battery life, content breadth) remain to be fully solved before XR is a mainstream, in-demand commodity. Thus, the field as a whole is best characterized as **on the cusp of scale (Level 6)**, rather than fully scaled.

**B) Sub-component breakdown:** It’s useful to note that within this bundle, **VR/MR headsets** are slightly more mature than **AR glasses**. Consumer VR (e.g. standalone headsets like Oculus/Meta Quest) has a several-million-user install base and a content ecosystem, roughly fitting a Level 6–7 (products delivered at scale with active competition)[27][28]. In contrast, true AR smart glasses (transparent, all-day devices) are at roughly Level 4–5: functional prototypes exist (e.g. HoloLens, Magic Leap, pre-release Apple glasses) and giants are heavily investing, but widespread deployment and cost reduction are still pending[2][11]. The **overall XR score of 6** is an approximate average of these states. We weight the score toward 6 because VR/MR’s success demonstrates the core technology’s feasibility and market value (pulling the average up), and AR glasses – while a step behind – are benefiting from the same advances in sensors, processors, and software. The **common functionality across variants (blending digital and physical worlds for human use)** means progress in one domain accelerates the others. Therefore, as a bundle, immersive AR/VR earns a solid Level 6: key

hurdles are actively being solved, early products are out, and the path to wider adoption in the next few years is credible – but the *final leap* to ubiquitous, everyday use (Level 7) will require further improvement in form factor, cost, and public demand as evidenced by future large-scale rollouts.

## ART 04.023 Brain-Computer Interfaces (BCI)

### 149. ART extraction

**A. Primary capability** – Direct, high-bandwidth communication between the human brain and digital systems, enabling users to send commands or information by *thought* and receive feedback without relying on conventional peripheral devices. This would bypass the speed and precision limitations of speech, typing, or touch by interfacing closer to neural activity. In essence, the ART promises a **brain-computer interface (BCI)** that can *read* neural signals (to decode intentions, imagined movements, attention, etc.) and *write* information back (via sensory feedback or direct neural stimulation), creating a seamless interactive loop.

### **B. Key sub-components / variants –**

- **Non-invasive BCIs (wearables):** External headsets or caps (e.g. EEG or optical imaging) that detect brain signals through the scalp, requiring no surgery. These prioritize safety and convenience but must overcome signal noise and limited bandwidth due to skull attenuation.
- **Minimally invasive BCIs:** Implanted electrode arrays that sit on the brain surface or within blood vessels (e.g. ECoG grids beneath the dura, or stent-electrode devices) without penetrating brain tissue deeply. These promise higher signal quality than wearables while reducing surgical risk relative to fully penetrating implants.
- **Fully implantable BCIs (intracortical):** High-density microelectrode arrays inserted into brain tissue, or advanced neural probes, capable of directly recording from and stimulating neurons. These offer the richest, high-bandwidth signals (and bidirectional capability) at the cost of invasive surgery and biocompatibility challenges.
- **Neural decoding & feedback systems:** Software and algorithms (often AI/ML-based) that interpret complex neural activity patterns in real time and translate them into control signals or device commands. These systems learn and adapt to each user's brain signals. Coupled with this are output modalities – from conventional visual/audio cues to **neurostimulation feedback** (stimulating the brain to convey sensory information or cues directly).
- **Packaging & connectivity:** The hardware is envisioned in wearable form factors (headsets) or fully implanted units with **wireless power and data** links. This includes on-board signal amplification/processing and secure wireless communication to external devices or cloud resources. Key engineering components are power management (to minimize heat), miniaturized electronics, and robust encapsulation to protect both the electronics and the brain over long durations.

### **C. Maturity indicators** – Evidence of progress for this ART would include:

- **Successful prototypes in humans (clinical trials):** e.g. paralyzed or locked-in patients

using BCI implants to control computers, communicate (typing or speech), or operate assistive devices in real-world settings. Repeated demonstrations of reliable, real-time control or sensation over months would show viability beyond isolated lab experiments.

- **High-channel, high-bandwidth devices demonstrated:** Hardware breakthroughs such as **large electrode-count implants with wireless data transfer** and long-term stability, or non-invasive systems achieving unprecedented resolution. Metrics like number of channels (order of 1000+), data rates (Mbps), and longevity of recordings/stimulation would indicate the bottlenecks of signal quality and scalability are being solved.

- **Movement toward commercialization:** Regulatory designations or approvals (e.g. FDA Breakthrough Device status, human trial approvals), **well-funded companies and consortia** building production prototypes, and **early product deployments**. For instance, multiple competing startups securing large investments and engaging in human trials, or partnerships with tech/medical device firms, suggest the field is transitioning from academic research to commercial development.

- **Ecosystem readiness:** Evidence of practical use-cases being tested (BCI-controlled consumer electronics, VR/AR integration, neuroprosthetic limbs with feedback, etc.), and the establishment of standards or safety protocols for neural data handling. Increasing participation of users outside the lab (at-home BCI use, externally monitored) and improving cost/power profiles would also mark a maturing technology.

#### 150. Evidence (10–20 recent, reliable sources)

151. **Wireless 65k-electrode BCI chip – Jung et al. (Columbia/Stanford/UPenn) – *Nature Electronics* (peer-reviewed) – Dec 2025.** **Link:** A fully implantable *subdural* BCI with a 50 µm-thick flexible chip (256×256 electrodes) was demonstrated[1][2]. It integrates 65,536 electrodes with 1,024 simultaneous recording channels and 16,384 stimulation channels, all on one CMOS chip, and communicates wirelessly at 100 Mbps (~100× higher throughput than prior wireless BCIs)[2][3]. This high-bandwidth implant, termed “BISC,” showed *chronic, reliable recordings* in pig cortex for 2 weeks and is designed to “slide” under the skull with minimal invasiveness[4][5]. **Significance:** Demonstrates a leap in scaling (orders-of-magnitude more channels) and system integration (on-chip processing + wireless power/data), tackling key bottlenecks of signal bandwidth and implant size for BCIs. It shows that high-density, *minimally invasive* BCIs are technically feasible and approaching clinical translation (studies in human patients were underway)[6][7].

152. **Endovascular BCI human trial – Mitchell et al. (University of Melbourne & Synchron) – *JAMA Neurology* (peer-reviewed) – Mar 2023.** **Link:** Reported the first *in-human* trial of a **minimally invasive** brain implant delivered via blood vessels (the “Stentrode” device) in four patients with ALS[8][9]. Over 12 months, the implanted endovascular electrodes remained stable with **no serious adverse events, no vessel blockage, and no migration**[8]. Neural signals (bandwidth ~233 Hz) were recorded reliably, and at least five distinct imagined movement commands could be decoded from each patient’s motor cortex activity[10][11]. All four users successfully used the BCI to control a personal computer for tasks like texting and emailing by thought alone[10][12]. **Significance:** Validates the safety and practicality of a **minimally invasive BCI** (inserted through the jugular vein, avoiding open brain surgery) over long-term use. It achieved real-world functionality – patients controlled digital devices hands-free – indicating a viable path to wider clinical deployment[13]. This also shows progress on a key maturity factor: multi-month home use is possible with an implant that greatly lowers surgical risk, supporting the plausibility of scaling BCI access to more patients.

153. **Brain-to-text/speech neuroprosthesis – Brandman, Stavisky et al. (BrainGate Consortium)** – *Nature / NEJM (peer-reviewed)* – Aug 2023 & Aug 2024. **Link:** A series of breakthroughs enabled **paralyzed patients to fluently communicate via BCI**. In one study, two intracortical implants (Utah arrays) recorded motor cortex signals from an ALS patient to decode intended speech at up to **62 words-per-minute** with ~25% error rate (Nature 08/2023). Subsequently, an improved BCI system translated neural signals into text *and* audible speech with **up to 97% accuracy**, as reported in NEJM[14][15]. The device (implanted in the speech motor cortex) allowed the user to converse by just attempting to speak – brain signals were decoded into phonemes and spoken aloud by a computer in real time[16][17]. Over 32 weeks, the system was used for 250+ hours of self-paced conversation, maintaining ~97% word accuracy with a large 125,000-word vocabulary after training[17][18]. *Significance:* These results shatter previous communication-speed records for BCIs, approaching natural speech rates and reliability. They demonstrate that *high-bandwidth* neural decoding paired with modern AI models can restore communication to nearly normal levels[19]. The sustained use and high accuracy achieved underscore the maturation of both the hardware (multi-array implants) and algorithms (deep learning decoding of neural activity), providing strong evidence that BCIs can meet real-world performance requirements for people with paralysis.
154. **Real-time speech BCI with low latency – Anumanchipalli & Chang teams (UC Berkeley/UCSF)** – *Nature Neuroscience (peer-reviewed)* – Mar 2025. **Link:** Researchers developed an **AI-driven BCI that streams neural activity to audible speech in near real time**[20][21]. Using a high-density electrode array on the cortical surface of a volunteer (an implanted ECoG grid) and novel streaming algorithms, they **eliminated the usual lag** in BCI speech prosthetics[21]. The system decoded the user's attempted speech and synthesized it into a voice output *almost instantaneously*, enabling a natural rhythm of conversation. Crucially, the approach generalized across different interface types: it was shown to work with intracortical microelectrode signals and even non-invasive electromyographic (EMG) sensors on the face[22][23]. *Significance:* Tackles a major usability challenge – latency – bringing BCI communication closer to normal human conversation speed[21]. It also suggests future BCIs could be modality-agnostic, using whatever signals available (invasive or non-invasive) with advanced AI decoding. This progress in software/algorithms complements the hardware advances, indicating the BCI field is addressing both sides of the “bandwidth” equation (neural signal capture *and* interpretation in real-time).
155. **Brain-spine motor bypass in human – Lausanne/EPFL (M. Courtine & G. Bloch)** – *Nature (peer-reviewed)* – May 2023. **Link:** A team in Switzerland demonstrated a **wireless brain-computer spinal interface** that enabled a chronically paralyzed man to regain natural walking ability[24]. An implant in the motor cortex captured the intention to move and transmitted it in real-time to a stimulator in the spinal cord below the injury, effectively forming a “digital bridge” over the lesion[24]. With this setup, the patient could stand, walk, and even climb stairs *controlled by his thoughts*, in outdoor and home settings[25][26]. Notably, after several months of use, the patient's neurological function improved to the point that some voluntary movement was possible even with the BCI turned off (suggesting activity-dependent plasticity). *Significance:* This is a milestone for *closed-loop BCIs* with both recording and stimulation: it validated that high-bandwidth neural signals can be used to restore complex motor functions in real life[25]. The work combines many aspects – implantable hardware, decoding algorithms, and neurostimulation – and shows the BCI can achieve **clinically meaningful outcomes (walking)**, underscoring the technology's transformative potential if matured. It also illustrates progress on safety/durability, as the system functioned reliably in daily activities, outside lab control.

156. **Non-invasive high-resolution BCI (DARPA “N<sup>3</sup>” program) – Grover et al. (CMU) –** *Journal of Neural Engineering / Univ. report* – Jul 2023. **Link:** Under a DARPA-funded project, researchers achieved **unprecedented spatial and temporal resolution in a fully non-invasive neural interface**[27][28]. By using novel electrode “patches” and tailored current injection patterns, they effectively made the skull “transparent” to electrical currents, focusing stimuli and recordings at specific brain regions with far greater precision than standard EEG or TMS[29][27]. In *animal studies* (rodents and monkeys), the team’s high-density wearable patches could steer currents to target motor cortex areas finely enough to distinguish adjacent hand/arm regions[30]. They built a platform to both **record and stimulate** brain activity through the intact scalp at high resolution, and as of 2023 they had progressed to initial *human testing (Phase 3)* with this technology[31][28]. **Significance:** Demonstrates that non-invasive BCIs need not be low-bandwidth forever – through advanced physics and engineering (flexible electronics, optimized waveforms), the team showed **it’s possible to dramatically improve signal focus without surgery**[27][32]. This addresses a key variant of the ART: if refined, such wearable BCIs could offer a safer, wide-access alternative for brain–computer communication. The fact that human trials are underway indicates a tangible path toward practical non-invasive BCIs with much higher performance than today’s EEG headsets.
157. **Paradromics “Connexus” high-data-rate implant – Paradromics Inc. –** *Company technical press release* – May 2023. **Link:** Paradromics announced an implant platform (Connexus Direct Data Interface) featuring **modular intracortical electrode units** and achieved an FDA Breakthrough Device Designation[33]. The system uses multiple small implants (“cortical modules”), each with **~1,600 channels**, linked to a subcutaneous hub for power and wireless communication[34]. By networking up to 4 modules, the device can record from 6,000+ neurons simultaneously – enabling *high data-rate streaming of brain signals*. The first target application is an assistive communication prosthesis to translate brain activity into text or speech in real time for patients with paralysis[35][36]. With a \$33 M Series A raise, Paradromics is preparing first-in-human trials for this system[37][33]. **Significance:** This illustrates the industry push toward **scalable, high-channel-count BCIs** and shows confidence from regulators (Breakthrough status) and investors in the technology. The Paradromics design emphasizes a path to manufacturing (leveraging multiple smaller implants rather than one huge array) and *high-bandwidth wireless data relay*[34][38]. It highlights that well-funded startups are now engineering devices not just for lab experiments but for *clinical translation*, with hardware and business roadmaps aimed at commercial deployment.
158. **Precision Neuroscience “Layer 7” cortical interface – Rapoport et al. (Precision) –** *Nature Biomed. Engineering (peer-reviewed) / industry news* – Oct 2025. **Link:** Precision Neuroscience (a Neurotech startup) published design and trial results for a **thin, flexible ECoG implant** that can be inserted through a *sub-millimeter slit* in the skull[39]. The device is a postage-stamp sized film, *only one-fifth the thickness of a human hair*, holding 1,024 electrodes; multiple modules can be combined (they’ve used up to four to cover 8 cm<sup>2</sup> of cortex)[39][40]. In a pilot with **5 human patients** (during brain tumor surgeries), the device recorded high-resolution neural data and even detected when a patient was trying to speak with ~80% accuracy after only 4 minutes of calibration[41][42]. The implant can also **deliver stimulation** without penetrating the brain, and in animal tests it recorded distinct signals from electrodes just 300 μm apart, indicating very fine spatial resolution[41][43]. The Layer 7 system received FDA clearance in 2023 for temporary intraoperative use (e.g. mapping brain activity during surgery)[44]. **Significance:** Validates a *minimally invasive* approach: high-density neural interfaces can be introduced with **no craniotomy and no penetrative probes**, significantly lowering risk[45]. Yet it still achieves “brain safety and performance” comparable to traditional electrodes[45]. The study also underscores momentum toward clinical adoption – FDA clearance and human data – and suggests such thin-film BCIs could be made *removable or*

*upgradable* (“modular and reversible” design), aligning with long-term maintenance needs at scale[39][46].

159. **Multimodal BCI integration & industry progress – (Summary of 2025 developments) –** *Fierce Biotech (trade news)* – Nov 2025. **Link:** By late 2025, the BCI sector saw **rapid commercialization efforts with multiple players**. Synchron, for example, raised \$200 M in a Series D to *expand operations and pursue FDA approval* of its **wireless Stentrode BCI**, which had by then been implanted in 10 patients across the US and Australia[47]. In 2023–25, a patient with a Synchron implant was able to **control an iPad and even an Apple Vision Pro headset by thought alone**, using the BCI to navigate apps, type messages, and interact with smart home devices (lights, Alexa) entirely hands-free[48]. Meanwhile, competitor Neuralink secured \$280 M (Jul 2023) and \$500 M (Sep 2024) in funding and began its first human trials, and other startups like Precision and Paradromics (USA) as well as *Science Corp.* (whose **retinal implant BCI restored partial vision** in AMD patients) made headline progress[49][50]. Companies are hiring aggressively and building out manufacturing/research facilities to develop **production-grade BCI devices**, and several devices have FDA Breakthrough status. *Significance:* Clear evidence of *multiple well-capitalized actors entering the final prototyping and trial phase* simultaneously[51][52]. There is a competitive race to bring BCIs to market, with fast-paced advances not just in labs but in *engineering, testing, and regulatory engagement*. The example of an ALS patient using a BCI with everyday consumer tech shows these interfaces are on the cusp of practical use outside research settings[48]. Collectively, these developments indicate that the field has moved beyond isolated experiments into a nascent **industry**, a key sign of growing maturity.

160. **Maturity score (1–7) and reasoning**

**Overall Maturity Score: 5** (out of 7) – **Advancing toward viable products:** Multiple converging BCI approaches have progressed through proofs-of-concept into active **clinical trials and pre-commercial prototypes**, backed by significant funding and institutional support. This corresponds to rubric level 5, where well-capitalized actors are racing to develop production-ready systems post-PoC and investing in scaling up the technology.

**Justification (Evidence-to-rubric mapping):**

- **Exceeds Levels 2–3 (theory & lab prototype):** BCIs are far past basic feasibility demonstrations. The core scientific principle – that neural signals can be recorded/decoded for device control – was established decades ago, and in recent years we’ve seen **robust prototypes working in human patients** for extended periods. For instance, the *12-month human trial of the Stentrode BCI* showed stable, safe operation and enabled everyday digital communication by thought[8][11], which is well beyond a lab demo. Similarly, intracortical BCIs have achieved unprecedented communication speeds (60–90 WPM) and accuracy ~97% in paralyzed users[15][19], indicating that fundamental technical hurdles (signal capture, decoding algorithms) have been solved to a degree that meets real user needs. These achievements rule out maturity levels 1–3 decisively.

- **Meets Level 4 (functional PoC):** The evidence shows **multiple functional PoCs hitting performance and viability targets**. Key breakthroughs – like the wireless 1024-channel BCI chip (BISC) that marries high bandwidth with minimal invasiveness[2][3], or the brain-spine interface restoring natural walking[24] – demonstrate that BCIs can deliver unique capabilities *beyond* what prior solutions offer. Many systems now operate untethered and user-friendly (wireless, wearable or fully implantable), a sign they are designed with eventual production in mind. Moreover, early **regulatory milestones** (e.g. FDA Breakthrough designations for multiple BCI devices[33][49]) and initial *at-home* uses (patients using BCIs

with tablets, VR headsets, etc. in daily life[48]) show that these prototypes are viewed as viable for deployment, not just isolated experiments. This solidly fulfills Level 4 criteria.

- **Approaching Level 5 (competitive development):** We assign **Level 5** because there is now a *competitive ecosystem of companies and research groups* driving the technology toward market. Over the last 2–3 years, at least a half-dozen well-funded startups (Neuralink, Synchron, Paradromics, Precision, Blackrock Neurotech, Science Corp., etc.) – often backed by major investors or government programs – have built BCI prototypes and are entering or conducting **clinical trials**[51][52]. They are explicitly working on manufacturable, implantable devices with the intent to commercialize in the near term (e.g. Synchron’s Series D to “accelerate commercialization” of its BCI, aiming for an FDA clearance and product launch)[51][53]. The **fast-paced progress** is evidenced by successive records and breakthroughs: higher channel counts and wireless throughput (scaling to thousands of electrodes and 100 Mbps links)[2][3], increasing numbers of human users, and integration with consumer technologies. Importantly, **no fundamental science roadblocks remain** – the focus has shifted to engineering reliability, safety, and user experience, which is characteristic of this stage. In summary, the groundwork for BCI’s core feasibility is done and the race is on to refine and deploy it, matching the description of level 5.

**Why not Level 6 yet?** BCIs have not fully reached widespread product delivery or scaling in the open market. *Level 6* would require that products are being delivered to many customers with expanding production and rapidly dropping costs. As of early 2026, BCI devices are still generally in the **clinical trial and early adopter phase** – e.g. dozens of human implants worldwide, not thousands; primarily in research or medical contexts rather than a general consumer market. We do see the first signs of future scaling (e.g. companies building manufacturing lines, multi-million-dollar investments for scaling, and some **limited commercial sales of simpler BCIs** like EEG headsets). However, the high-bandwidth, implantable systems described in the ART are *just entering* pivotal trials and have not yet seen mass deployment or revenue-generating sales. No competing products are broadly on the market for end-users yet (aside from niche research and medical use). Achieving level 6 will likely require regulatory approvals and initial commercialization – for example, an FDA-approved BCI for paralysis available to hospitals/clients, with units being produced and sold – which is anticipated within a few years but not reality at present.

**Sub-component nuances:** This ART spans a spectrum from non-invasive to fully invasive BCIs, which are at slightly different maturity stages. **Non-invasive BCIs** (e.g. EEG wearables) are *technologically simpler* and some are **already commercial** (for wellness, gaming, etc.), but currently they offer limited bandwidth and have not proven the transformative value described (they largely remain niche gadgets). **Implantable BCIs** (both minimally invasive and penetrating types) are where the highest performance lies and where recent progress is fastest – these are in clinical trials with strong results but not yet sold products. If we were to score separately: non-invasive BCI tech might be around *Level 6 in terms of product availability* (since EEG devices are sold), but perhaps *Level 3–4 in terms of achieving the high-bandwidth promise*. Invasive BCIs are about *Level 4–5* (successful prototypes and entering production trials). On balance, because the **ultimate value proposition** of the ART (high-bandwidth, reliable brain–computer links) is being driven primarily by the invasive and minimally invasive implementations, the overall maturity is taken as **Level 5** – reflecting the leading edge where multiple groups are actively transitioning those high-performance BCIs from lab to market. This single score represents an **aggregate view** of the full BCI technology

bundle: core functionality has been demonstrated with clear benefits, and the field is now in the competitive development phase on the cusp of initial commercialization, but has yet to achieve wide deployment or a mature market ecosystem.

## ART 04.024 Advanced Prosthetics & Exoskeletons

### 1. ART extraction

- **Primary capability:** Wearable robotic prostheses and exoskeletons that *restore or enhance human mobility and strength* by tightly integrating with the user's body and neural control signals. These systems aim to act as natural extensions of the body, allowing amputees to move prosthetic limbs intuitively and able-bodied users to amplify strength or endurance in daily tasks.
- **Key sub-components/variants:**
  - **Neuro-integrated prosthetic limbs:** Robotic arms or legs that interface with muscles or nerves (via EMG sensors, nerve implants, etc.) for intuitive control and that provide **haptic feedback** (touch/pressure sensations) back to the user.
  - **Powered exoskeleton suits:** Rigid full-body or limb frameworks worn externally (over clothes or integrated into garments) to **support and amplify movement** (e.g. enabling paralyzed users to walk, or workers to lift heavy loads with reduced effort). Includes **soft exosuits** using textiles and lightweight actuators for assistive support.
  - **Advanced actuators & sensors:** Lightweight, high-torque **electric actuators** (with low noise and high backdrivability) and dense sensor arrays (motion sensors, force/pressure sensors, etc.) embedded in the device to closely monitor user movement and intent.
  - **Adaptive control and AI:** **Adaptive software control systems** (often with machine learning or model-based control) that interpret user intent (from muscle signals, body posture, or even brain signals) and adjust assistance in real time. These systems use **pre-trained models with ongoing user-specific calibration** to improve over time, adjusting for posture changes, fatigue, or specific tasks.
  - **Interface methods:** Both **non-invasive interfaces** (surface EMG electrodes, smart wearable controllers, voice or smartphone commands) and **invasive interfaces** (surgically implanted electrodes in muscles or nerves, osseointegrated bone anchors with wired feedthroughs) are being explored to improve signal reliability and bidirectional communication with the nervous system.
  - **Haptic feedback mechanisms:** Various techniques (vibratory motors, pressure pads on skin, nerve stimulation implants) to **return sensory feedback** (touch, proprioception) to the user, closing the loop for more natural control of prosthetic or exoskeletal limbs.
- **Maturity indicators (evidence to look for):**
  - *Human trials and field deployments:* Successful **clinical trials or real-world tests** of prosthetic/exoskeleton systems (e.g. amputees performing tasks with neurally controlled

bionic limbs; paralyzed patients walking with exoskeletons; workers using exosuits on job sites) demonstrating safety and functional improvements.

- *Proof-of-concept breakthroughs*: Published experiments showing resolution of key challenges – e.g. a prosthetic hand with multi-finger touch feedback enabling complex manipulations, or an exoskeleton auto-adjusting assistance based on user fatigue.
- *Regulatory approvals and standards*: **Regulatory clearances (FDA, CE, etc.)** for devices, inclusion in clinical guidelines or insurance policies, and development of safety/performance standards – indicating the tech is moving from lab to market.
- *Commercial products and adoption*: Evidence of **products in production and sale** – for instance, units shipped or revenue from exoskeleton companies, hospitals or rehab centers adopting exoskeleton programs, military or industry purchasing these devices.
- *Ecosystem and competition*: Presence of **multiple companies and research teams across regions** investing in the technology – e.g. well-funded startups and major biomedical firms launching products, government or defense contracts for exosuits, and international research consortia/roadmaps – signaling competitive drive and progress toward scalable manufacturing and cost reduction.
- *Performance metrics near practical thresholds*: Achievements in battery life, device weight, lifting capacity, response latency, etc., that approach the requirements for everyday use (for example, an exoskeleton that runs an 8-hour work shift or a prosthetic hand performing tasks as quickly as a natural hand). Evidence that costs are coming down or will with scaling (e.g. described cost range comparable to cars/machinery) would also indicate maturation toward wider deployment.

## 2. Evidence (10–20 recent, reliable sources)

- **Multichannel haptic feedback unlocks prosthetic hand dexterity** – Moaed A. Abd et al., *Scientific Reports* (peer-reviewed) – Feb 2022.  
*Researchers demonstrated a soft robotic armband that provides multi-channel haptic feedback to upper-limb amputees using a dexterous prosthetic hand. With distinct tactile feedback for each finger, subjects could simultaneously grasp and carry two objects without visual cues, completing tasks faster and without dropping or crushing the items[1][2]. This shows that rich sensory feedback can dramatically improve prosthetic hand control, tackling a major challenge (the one-grip-at-a-time limitation) and making the prosthesis feel more like a natural extension.*
- **Restoration of natural somatic sensations to amputees (neurostimulation study)** – Soghoyan et al., *Frontiers in Neuroscience* (peer-reviewed) – accepted Oct 2024 (open-access via NIH PMC).  
*Reports a trial with two transhumeral amputees who received implanted electrodes in peripheral nerves and spinal cord. By electrically stimulating these interfaces, the users felt tactile and proprioceptive sensations in their missing hand, which enabled them to discriminate object sizes and softness using a bionic hand[3]. Over practice, the sensations became more natural and helped reduce phantom limb pain[4][5]. This demonstrates a feasible bidirectional neural interface in humans – a key proof-of-concept for prosthetics that “feel” and respond like biological limbs.*
- **Emerging value of osseointegration for intuitive prosthetic control (systematic review)** – Alessandri-Bonetti, Peretti, Aszmann et al., *PRS Global Open* (peer-reviewed) – 2024.  
*A review of transhumeral (above-elbow) amputees using bone-anchored prostheses. It finds that osseointegrated prosthetic implants (which rigidly fix the prosthesis to the skeleton and can house electrode connections) led to significantly improved range of motion and daily*

function compared to traditional socket-mounted prosthetics. Notably, “one study demonstrated [that] an osseointegrated implant [can serve] as a bidirectional gateway for signal transmission, enabling intuitive control of a bionic hand.”[6]. In essence, the prosthesis can directly tap into the user’s nerves/muscles through the bone implant, allowing more natural mind-controlled movement and sensation. This highlights a path to reliable, long-term integration of prosthetic limbs with the body’s neuromuscular system.

- Somatosensory restoration and neural control strategies in lower-limb prostheses** – D.M. Mariscal, B. Driscoll, H. Huang, L.E. Fisher et al., *npj Biomedical Innovations* (review) – Dec 2025.

A comprehensive review of technologies for bidirectional lower-limb prosthetics. It notes that while most prosthetic legs are still passive or autonomously-controlled, powered limbs have emerged (e.g. Össur’s Power Knee, Ottobock’s Empower ankle) and some are commercially available across different countries[7]. These powered knees/ankles improve walking but lack direct user neural input, so the review discusses recent efforts to bridge that gap with neural interfaces. For example, systems to stimulate nerves for feeling from a prosthetic foot and to capture signals from residual muscles for more responsive control are in development[8]. The review underscores that multiple teams are now integrating invasive and non-invasive interfaces to create truly “smart” prosthetic legs, reflecting rapid progress built on the successes of upper-limb bionics.
- Leveraging LSTM, tactile sensors, and haptic feedback to augment prosthetic control** – Sudhir S. Zhuwawu & Haitham El-Hussieny, *Scientific Reports* (peer-reviewed) – Aug 2025.

Demonstrates an AI-driven approach to more intuitive prosthetic hand use. The team equipped a prosthetic hand with soft fingertip tactile sensors and used a trained LSTM neural network to classify the type of grasp the hand was performing. They provided the user with a unique vibrotactile feedback pattern for each grasp type. In real-world tests, the system could predict the grasp within <1 s with ~87–89% accuracy and cue the user via haptics[9]. This allowed users to know the hand’s grip state without looking, improving decision-making and control[10][11]. Such adaptive, intelligent control – combining sensor data, machine learning, and user feedback – shows the plausibility of prosthetics that partly “understand” their own state and assist the user in operating them more naturally.
- Molina Healthcare Clinical Policy: Powered Exoskeleton for Ambulation** – Molina Healthcare (insurer technical policy) – updated Oct 2025.

Summarizes the regulatory and clinical status of lower-body exoskeletons in the U.S. healthcare system. It notes that multiple robotic exoskeletons have FDA 510(k) clearance (product code PHL) for rehabilitation use, including the ReWalk, Ekso GT, Indego, and ExoAtlet-II devices[12]. Initially approved for spinal cord injury paraplegia, indications have expanded – e.g. “In June 2022, the EksoNR became the first exoskeleton approved for patients with multiple sclerosis,” and in “March 2023, the ReWalk Personal Exoskeleton received FDA approval for use on stairs and curbs.”[13][14]. Furthermore, two devices (ReWalk and Indego) are approved for personal/home use[15]. This is strong evidence of maturation: the technology has moved into real clinical deployment, with regulatory bodies acknowledging improved safety/function (even tackling challenges like stair-climbing) and insurers evaluating coverage.
- Ekso Bionics Reports Record Annual Revenue of \$18.3 Million** – Ekso Bionics (press release, via Globe Newswire) – Mar 4, 2024.

Ekso Bionics, a leading exoskeleton manufacturer, announced that in 2023 it sold 151 exoskeleton units (EksoHealth devices for rehabilitation), a record high, driving a 42% year-over-year revenue increase to \$18.3 M[16]. The company attributes the growth to “strong demand” and notes expanding use “across the continuum of care from hospital to home”[17].

*This commercial evidence shows that powered exosuits are not just experimental – they are shipping in growing numbers to real customers. With a NASDAQ-listed company and rising sales, it indicates competition and investment in scaling up production, and suggests that costs may gradually decrease with volume. (For context, a single unit can be priced on the order of a new car, so economies of scale are crucial.)*

- **Hands-free Atalante exoskeleton in post-stroke gait and balance rehabilitation: a safety study** – A. Delva et al., *Journal of NeuroEngineering & Rehabilitation* (peer-reviewed) – 2025. Evaluated the French-made Atalante X exoskeleton (a self-balancing, hands-free lower-body exosuit by Wandercraft) in a multi-center trial with 40 stroke patients. After 5 training sessions, no serious device-related adverse events occurred; 82.6% of participants completed a usability test and 90% reported satisfaction with the exoskeleton[18]. Significant improvements in gait speed, distance, and balance scores were observed post-training ( $p < 0.05$ )[19]. The authors conclude the device is safe, feasible, and well-tolerated for post-stroke rehab, warranting larger trials[20]. This is a concrete demonstration of an advanced exoskeleton being used on actual patients: it validates not only the engineering (battery-powered dynamic walking with no need for crutches) but also user acceptance. Such field trials are a critical maturity milestone on the path to routine clinical adoption.
- **German Bionic Apogee Exosuit Debut at CES 2023** – German Bionic / MassRobotics news blog – Jan 2023. Describes the launch of the German Bionic Apogee, a 5th-generation industrial exoskeleton. The Apogee is an AI-supported, network-connected wearable that provides up to 30 kg of lower-back lifting assistance per lift and active walking support to reduce fatigue and injury[21][22]. It is dust- and water-resistant and designed for everyday workplace use. The suit won the CES 2023 “Best of Innovation (Wearable Technologies)” award and garnered media attention from Wired, AP, Reuters, etc., highlighting it as a “cool” and practical innovation. This indicates that powered exosuits are moving toward mainstream recognition in industry. The Apogee’s specs (significant lift assist, ergonomic design) and accolades show that vendors are addressing real-world requirements (comfort, durability, data connectivity) needed for scaling in industrial and logistics environments.
- **ReWalk 7.0 Personal Exoskeleton & FDA clearances** – Lifeward/ReWalk Robotics (press info via CMS and company IR) – 2023–2024. ReWalk Robotics, a pioneer in rehabilitation exoskeletons, has incrementally improved its personal exosuit and navigated regulatory hurdles. In 2023, the FDA cleared an update allowing the ReWalk Personal 6.0 exoskeleton to be used on stairs and curbs[23], a first for a personal wearable robot. By 2024, U.S. Medicare assigned a billing code (K1007) for exoskeletons and is evaluating reimbursement, and ReWalk announced a new model (ReWalk 7.0) with cloud connectivity and adjustable speeds[24]. These developments show both technical progress (expanding device capability from level surfaces to stairs) and growing institutional acceptance.\* Inclusion in the healthcare reimbursement system is especially telling: it implies the technology is considered efficacious enough to justify cost coverage, which will drive broader adoption once final payment policies are in place.

*(Additional context: Outside the healthcare domain, exoskeletons have seen interest from militaries (e.g. U.S. Marines and Air Force testing Sarcos’s Guardian XO for heavy lifting[25][26]) and automotive manufacturers (Hyundai, Toyota, GM, etc. developing wearable assist devices for factory workers). Major prosthetics companies (Ottobock, Össur) have also acquired exoskeleton startups and are investing in “bionic” limb tech. Such cross-sector activity supports the notion that advanced prosthetics & exosuits are moving toward a commercial scaling phase.)\**

### 3. Maturity score (1–7) and reasoning

**Final Score: 6** (Early Commercialization/Scaling Phase)

**A) Why not lower:** The evidence shows this ART is **well beyond lab demonstrations (Levels 2–3)**. We have multiple **functional prototypes and PoCs solved (Level 4)** – for instance, neural interfaces enabling amputees to feel and control prosthetic limbs in trials[3], and exoskeletons that allow paraplegics to walk and even climb stairs[14]. Crucially, we also see **post-PoC product development and delivery (Levels 5–6)**: at least five competing companies (ReWalk, Ekso Bionics, Indego/Parker, ExoAtlet, Wandercraft, etc.) have brought medical exoskeletons to market with regulatory approval[12], and new entrants like German Bionic and Sarcos are pushing industrial exosuits. Sales figures – e.g. 151 rehab exos sold in one year[16] – and expanding use cases (SCI to stroke to MS patients[13]) show **growing customer adoption and investment**, which rules out Level 4 or 5 (where technology would still be in prototype or pilot-deployment stage). In essence, the core capabilities of this ART (powered wearable mobility devices) have been **proven viable and are already helping users outside the lab**, a hallmark of Level 6 maturity.

**B) Why not higher:** The technology hasn't yet reached wide, exponential adoption or full maturity in all aspects, which prevents a Level 7 rating. Many deployments today are still in controlled or niche environments (hospitals, rehab centers, pilot industrial sites) rather than ubiquitous use. **Customer demand, while rising, remains limited by high costs and ergonomic constraints**, and companies like Ekso Bionics are still in the process of achieving profitability (sales are growing but in the low hundreds of units, and external funding is still important[17][27]). Moreover, some of the most “radical” features – for example, surgically integrated prosthetics with seamless brain-level control and realistic sensation – are *just entering early clinical trials*, not yet commercialized. The evidence shows important breakthroughs (like an implanted interface letting an amputee intuitively control a robotic arm[6]), but these remain case studies or limited series at present. To justify Level 7, we would expect **mass-market competition and self-sustaining growth** – e.g. thousands of units annually, major reductions in price, and these devices becoming common in everyday workplaces or standard care for disabilities. That scenario is still unfolding. In summary, the **overall domain is in a Level 6 stage**: real products exist and are improving quickly, new players continue to enter, and early adopters are seeing value – but the technology is not yet a widely adopted commodity across its potential applications, and some sub-technologies need a bit more maturation to reach the next stage.

**C) Sub-component breakdown:** This ART spans somewhat distinct fronts – high-integration neuroprosthetics versus wearable exoskeletons – which are at **different maturity levels** today:

- **Medical & rehabilitative exoskeletons: Level 6.** Multiple FDA-cleared products are on the market and being delivered to hospitals and personal users[12][16]. Companies in the US, EU, and Asia are improving these devices' capabilities (e.g. use on stairs, hands-free balancing) and scaling up production. There is active competition and even progress toward insurance reimbursement, indicating a transition from experimental to standard-of-care (e.g. stroke rehab trials showing safety and benefits[18][20]). This segment sees internal R&D investment by firms and some economies of scale emerging, consistent with early Level 6 characteristics.

- **Industrial/military exosuits: Level 5 (~5 to 6).** This overlaps with the above but focuses on augmenting able-bodied workers. We see well-capitalized efforts (Sarcos, Hyundai, German Bionic, etc.) deploying prototypes and first-gen products (some units in field trials with logistics companies and military tests) – for example, an exosuit lifting 30 kg repeatedly won innovation awards[21]. However, widespread adoption in workplaces is just beginning, and many such projects are still seeking the optimal balance of cost, power, and usability. There are signs of rapid progress (venture funding, partnerships like Sarcos with airlines and the U.S. Air Force), but until these suits become common equipment for factories or construction, this sub-field sits at high Level 5 or entering Level 6.
- **Advanced prosthetic limbs (with neural control & feedback): Level 3–4.** Here the fundamental science is proven and **lab prototypes** have shown that implanted sensors/stimulators can restore naturalistic control and sensation[3]. There is **clear academic and clinical interest** (with breakthroughs published in top journals and pilot patients gaining functions previously impossible). However, these solutions are largely in research or early clinical feasibility stages – not yet widely productized. Only a handful of patients worldwide have received fully implanted, brain- or nerve-integrated prosthetic systems to date. Thus, this sub-component is around Level 3 (experimental demonstrations) pushing into Level 4 (initial proof-of-concept in real use conditions). It will need further engineering for reliability, plus regulatory and manufacturing advances, to catch up with the exoskeleton realm.
- **State-of-practice prosthetics (myoelectric bionic limbs without invasive interface): Level 6.** It's worth noting that current high-end prosthetic arms and legs – such as multi-articulated hands (Ottobock Bebionic, Touch Bionics i-Limb) or microprocessor knees and ankles – are **established products**. They leverage simpler control methods (surface EMG signals, pre-programmed patterns) and have seen moderate adoption for decades. Their presence indicates that the *baseline technology (robotic limb hardware)* is mature. The ART description, however, is about **radically enhancing these with closer integration and feedback**, which is why we emphasize the Level 3–4 status of those novel features rather than the legacy devices themselves.

Considering these sub-scores, the overall **integrated score is chosen as 6**. We weighted the exoskeleton progress more heavily in the average because exoskeletons are a major part of the ART's value proposition (reducing physical burdens for many people) and are closer to commercialization at scale. In essence, wearable exosystems are already entering the market (dragging the average upward), while neural prosthetics are a step behind but on a fast track. The **bundle's functionality – augmenting human mobility – is being realized in practical products (exoskeletons) now**, even as the full vision (especially for neural prosthetics) will unfold over the next decade. This justifies a **Level 6**: the field as a whole has clearly moved into early market deployment, with momentum toward wider growth, though not yet a ubiquitous technology.

## ART 04.025 Haptic and Multi-Sensory Feedback Systems

### 161. ART extraction

162. **Primary capability – “rich touch” feedback:** Enable users to precisely *feel* and control artificial limbs, tools, or virtual objects through advanced haptic feedback. This entails recreating a wide range of tactile sensations (pressure, texture, temperature, motion, limb/tool position) in real-time, far beyond today’s simple buzz or force cues. The goal is fluid, fine-grained manual control with sensory realism, closing the loop between user actions and feedback.
163. **Key sub-components/variants:**
- **High-density sensors & actuators:** Arrays of miniaturized pressure sensors and haptic actuators (vibrational motors, microfluidic or electroactive elements, etc.) to achieve high spatial resolution and varied stimuli. For example, flexible “electronic skins” with densely packed sensing and feedback pixels[1][2].
  - **Multi-modal feedback mechanisms:** Multiple stimulation modes combined – e.g. **force/pressure** actuators for weight or resistance, **vibrotactile** actuators for texture/fine touch, **thermal** elements for hot/cold, and even **electrical/nerve stimulation** for direct neural feedback[3]. Wearable devices may integrate force + vibration + temperature in one system to enrich the sensation palette.
  - **Wearable and integrative form factors:** Haptic interfaces embedded in soft, skin-like materials (gloves, clothing, patches) or **woven into textiles**, as well as **prosthetic interfaces** implanted or attached to the body (e.g. nerve-connected prosthetic hands). Variants range from haptic VR gloves and full-body suits to feedback-equipped exoskeletons and neuroprosthetic implants.
  - **Signal processing & adaptive control:** Real-time controllers and AI algorithms that modulate actuator signals based on sensor inputs and user context. This provides *closed-loop feedback* with low latency (within milliseconds), adapts intensity to user preference, filters noise, and can learn from usage patterns to improve the feedback relevance over time.
164. **Maturity indicators (evidence of progress):**
- *Laboratory prototypes demonstrating multi-sensory feedback:* e.g. research devices that combine multiple haptic modalities (force + vibration + temperature) and show improved user performance or realism in tasks.
  - *User trials and proofs of concept:* Testing with humans (including amputees or operators) that show the technology restores sensations (touch, proprioception) and improves control or reduces errors[4][5].
  - *Integration into functional systems:* Working demos of feedback-enabled prosthetic limbs or VR/AR gloves operating in real-world scenarios (rehabilitation tasks, virtual training, tele-surgery, etc.), indicating practical viability (comfort, safety, robustness).
  - *Early commercial prototypes or products:* High-end haptic gloves, suits, or prostheses entering limited markets (e.g. enterprise or medical devices) – with published specifications on feedback resolution, response time, durability, and initial cost – signaling a transition from research to scalable engineering[6][7].
  - *Multiple active R&D programs:* Significant funding, startups, or industry initiatives (in at least two regions) focused on advanced haptics – suggesting

competition to refine prototypes for production (improving weight, power consumption, materials, and cost towards broader deployment).

165. **Evidence (10–20 recent, reliable sources)** (*All sources are from the last 4 years*)
166. **Multi-modal wearable haptics – review (2022):** *Ya Huang et al., Materials Today Physics, Jan 2022*. A peer-reviewed review that highlights the need to combine different haptic feedback modalities (force, thermal, electrical/nerve stimulation) in wearable interfaces. It notes that single-mode haptic devices each have shortcomings, and that integrating multi-mode feedback can significantly improve realism and overcome current challenges for VR/AR and robotics[3][8]. This underscores the plausibility of the ART’s core idea that richer, multi-sensory feedback is both necessary and being actively pursued.
167. **Tactile sensor advances for rich feedback (2025):** *Hothefa S. Jassim et al., Biosensors and Bioelectronics: X (peer-reviewed review), Oct 2025*. This article surveys recent progress in tactile sensing technologies for human–robot interaction. It documents new **mechanoreceptor-mimicking sensors** (piezoresistive, capacitive, piezoelectric) with enhanced sensitivity and flexibility, and addresses how challenges in scalability, durability, and cost are being tackled[9]. These advances in high-density, robust tactile sensors support the feasibility of dense sensor arrays needed for fine-grained haptic systems. Integration of such sensors with AI (for self-learning feedback tuning) is also discussed[10], aligning with the ART’s vision of adaptive, smart feedback loops.
168. **Flexible haptic actuators for wearables (2025):** *Wei Wang et al., Nano Research (Review), Aug 2025*. A comprehensive review of **flexible, lightweight haptic actuators** that can be comfortably worn. It explains that traditional haptic devices were often bulky and rigid, limiting long-term use, whereas new designs using soft materials, textiles, and compliant structures can deliver forces and vibrations while conforming to the body[11]. The article surveys material and actuation innovations (electroactive polymers, microfluidics, flexible electromagnetic actuators, etc.) and shows how these enable wearable haptics in VR, teleoperation, and healthcare. This suggests that practical constraints of weight and comfort are being addressed by current research, increasing the plausibility of all-day wearable feedback systems.
169. **Wireless e-skin with touch sensing & feedback (2022):** *Dengfeng Li et al., Science Advances 8(51): eade2450, Dec 2022*. Researchers at CityU Hong Kong demonstrated a **soft electronic skin patch** (7×10 cm, ~4 mm thick) with a 4×4 array of “actuator pixels” that double as pressure sensors[12]. The wireless patch (Bluetooth-enabled) can both detect a user’s touch and reproduce it on a remote user’s patch in real-time, effectively enabling two-way touch communication (“touch IoT”)[13][12]. Pressing on one patch generates corresponding pressure/vibration on the other. This prototype proves the concept of a self-contained, multi-user haptic network and demonstrates millisecond-range closed-loop feedback in a wearable format, directly supporting the ART’s feasibility (rich touch feedback, networking, robustness for remote interaction).
170. **Multi-directional skin actuator (Science 2025):** *Kyoung-Ho Ha, Jaeyoung Yoo, Shupeng Li, John A. Rogers, Yonggang Huang et al., Science, Mar 2025*. A peer-reviewed breakthrough reporting a **“full freedom-of-motion” haptic actuator** about the size of a coin that can apply forces to the skin in any direction – not just normal vibration, but also stretching, shear (sliding), and twisting forces[14]. The device is compact, battery-powered, and wireless (Bluetooth), and multiple actuators can be arrayed on the body. It can combine different motion stimuli and operate with finely programmable intensity and timing, creating unprecedentedly realistic touch sensations[14][15]. This achievement demonstrates scientific feasibility: it shows that hardware can generate a rich palette of tactile cues at high fidelity.

Published in a top journal, it provides strong evidence that ultra-refined haptic feedback (with multi-axis, multi-modal output) is no longer just theoretical but has been experimentally realized in the lab.

171. **Nerve-interface prosthetic sensation (2023):** *Paul Čvančara et al., npj Flexible Electronics 7:51, Nov 2023.* This open-access study reports on *implanted* thin-film electrode arrays (polyimide-based intrafascicular electrodes) that provided sensory feedback to three human amputees using prosthetic hands. The implants in the arm nerves remained stable and functional for up to 6 months, with **no signs of corrosion or degradation** and **consistent, precise elicitation of sensations** over the entire period[16][17]. Users could reliably feel touch/pressure via nerve stimulation when using their bionic hand. This evidence shows both plausibility (closed-loop neural feedback in prosthetics works in practice) and improving maturity – addressing safety/longevity for permanent implantation, which is crucial for real-world prosthetic adoption. It confirms that connecting haptic systems directly to nerves (one of the more radical aspects of the ART) is actively being tested with promising results.
  
172. **“HaptiYarn” textile haptics (2024):** *Pasindu Lugoda et al., IEEE Transactions on Haptics 17(4):964-969, Oct–Dec 2024.* Demonstrates a novel approach to make haptic systems lightweight and unobtrusive by weaving actuators into clothing. The team developed **HaptiYarn – an actuator yarn** that can be knit into garments[18]. Each yarn, controlled by micro-scale pneumatic pulses, can expand radially (~28 mm displacement) to squeeze the body at precise spots. Integrated graphite nanoparticles in the elastomer yarn improved durability (withstood >7,500 cycles without performance loss)[19]. They created a prototype VR vest with 8 such yarn actuators, enabling the wearer to “feel” immersive feedback (like virtual hugs or impacts) across the torso[20]. This is evidence of practical engineering progress: haptic feedback delivered via ordinary textiles, maintaining comfort and breathability. It addresses the ART’s concern for wearability and shows a path to high-density actuator integration using advanced materials and fabrication (supporting the idea that specialized manufacturing – here, multi-layer yarns – can produce robust yet flexible haptic devices).
  
173. **High-resolution tactile sensor array (2025):** *Chengran Cao et al., (MDPI open-access), accepted Aug 2025.* Reports a **256×256 tactile sensor array** with microscale structured sensors achieving **spatial resolution of 0.5 mm** – finer than a human fingertip’s ~1 mm discrimination threshold[1][2]. The sensors use 10 μm pyramidal microstructures and a CNT-based resistive layer, yielding ultra-high sensitivity (~8.1 kPa<sup>-1</sup> in the low-pressure regime) and detection of very light touches (down to 90 Pa)[1]. The array, coupled with a thin-film transistor readout, successfully captured and reconstructed subtle textures such as Braille dots and 500 μm surface patterns[21][2]. It also demonstrated good response speed (~125 ms) and stability over 1000+ cycles. This is a key enabling tech for the ART: such high-density, high-sensitivity sensor arrays could allow artificial limbs or haptic devices to *sense* texture and pressure with human-like (or better) fidelity, which can then be fed back to the user. The manufacturing approach (molded microstructures + solution processing) is noted as scalable[22], suggesting a path toward cost-effective production – partially addressing the ART’s manufacturing and cost bottlenecks.
  
174. **Multi-modal prosthetic feedback trial (2023):** *Emre Sariyildiz et al., Sensors 23(20):8492, Oct 2023.* This experimental study evaluated a **hybrid haptic+proprioceptive feedback system** on a prosthetic hand. The setup combined a **mechanotactile pressure feedback** (applying proportional force on the user’s arm corresponding to the prosthetic’s grip force) and **vibrotactile feedback** to signal discrete hand aperture (grip positions)[23]. In tests with 32 able-bodied participants (using a prosthetic simulator): (i) With tactile feedback, users could better judge how much force the bionic hand was applying (though some

underestimation occurred at higher forces). (ii) With proprioceptive (vibration) cues, participants **identified four different hand positions (open, wide, narrow, closed) with 100% accuracy** without visual cues[24]. (iii) Using both feedback modes, subjects could recognize objects of different shape and stiffness with **90.5% overall accuracy**[24]. Notably, these results were consistent across different feedback locations on the arm and muscle states. This study is evidence that multi-sensory feedback improves functional outcomes: it shows plausibility that an artificial hand with such feedback can restore complex perception (object differentiation by touch) and confirms maturity beyond theory – a closed-loop *proof-of-concept* in humans, using relatively simple, non-invasive hardware (force pads and vibrators on the skin).

175. **Thermal feedback in prosthetics (2024):** *Jonathan Muheim et al., Med (Cell Press) 5(2):118-125, Feb 2024.* Reports the first successful integration of **temperature feedback** in a prosthetic hand. Researchers exploited “phantom thermal sensation” – by heating/cooling specific spots on an amputee’s residual arm, they induced the feeling of warmth or coolness *in the missing (prosthetic) hand*. They built a standalone thermal feedback module into a commercially available bionic hand and conducted a long-term single-case trial[25][26]. The amputee could distinguish hot, cold, and ambient objects, different material properties (metal vs plastic), and even tell an artificial hand from a human hand via warmth, with **accuracy comparable to his intact hand**[26]. In a standardized test (400+ days span, 15 sessions), he consistently sorted objects by temperature correctly in real time. No adverse effects were reported, and the phantom thermal sensations remained stable over 13 months[27][28]. This is a notable milestone for multi-sensory haptics: it adds the thermal modality to the feedback mix and demonstrates viability in a real-world scenario (integrated with a prosthetic used in daily life). It indicates increasing maturity – not only are such systems being prototyped, but they are now tested with end-users under extended timelines, an important step toward clinical adoption.
176. **Haptic feedback reduces robotic surgery error (2025):** *Hironobu Takano et al., Journal of Robotic Surgery 19(1):662, Oct 2025.* This study investigated the impact of adding haptic force feedback to a surgical tele-robot (in a cadaveric experimental setup). Six surgeons performed robotic tissue manipulation tasks with either no feedback, moderate feedback, or full force feedback. The key finding was that **grip forces significantly decreased as haptic feedback was added**[5] – surgeons squeezed more gently when they could feel resistance, which is critical for preventing tissue damage. Task completion time and motion efficiency didn’t change much, but from a safety perspective this is big: haptic feedback “suggested enhanced surgical safety” by curbing excessive force[5]. This evidence speaks to the value proposition of the ART – in domains like telesurgery (or any remote/robotic operation), richer feedback reduces errors and improves control. It also shows that such feedback systems have moved into realistic testing (surgery scenarios), indicating a growing maturity in specialized applications (medical robotics).
177. **Enterprise-grade haptic gloves shipping (2023):** *HaptX (industry product announcement), as reported by UploadVR – Ian Hamilton, Oct 2022.* HaptX, a well-funded haptics startup, moved from prototypes to a production model with its **“Gloves G1” haptic gloves**. These gloves use hundreds of microfluidic air actuators that displace the user’s skin to simulate touch and force feedback. The G1 system includes a 17-pound backpack air compressor and was offered for enterprise pre-order at ~\$5,500 per pair (with ~\$500/mo subscription)[6][7]. Shipping was planned for Q3 2023 to industrial and research customers. While still expensive and not consumer-focused, this marks one of the first commercially available, full-featured haptic wearable products. The high density of actuators and the presence of a few such companies (HaptX, and others working on gloves or suits) show that

the technology is transitioning from lab to market. It validates the ART's assumption that initial costs would be comparable to high-end equipment and that early adoption is in specialized markets. The existence of a production-ready glove with multi-point feedback confirms a level of technical maturity (meeting safety, integration, and reliability requirements for sale) and underscores that multiple actors are in competition to solve remaining issues (reducing size/weight – e.g. Meta's Reality Labs prototype gloves – and lowering cost).

178. **Maturity score (1–7) and reasoning**

**Overall Maturity Score: 4 (Proof-of-Concept demonstrated, nearing prototype stage).**

**Justification:** The evidence above rules out the lower maturity levels – this is far beyond theoretical (Level 1) or initial lab observation (Level 2). We now have **multiple working prototypes and demonstrations (Level 3+)** solving key technical hurdles: e.g. a multi-modal haptic patch and glove arrays[13][14], a prosthetic hand with multi-sensory feedback tested over months[26], and sub-millimeter sensor/actuator resolutions[1]. Crucially, there are **integrated proof-of-concept systems (Level 4)** that meet core functionality requirements: the Science 2025 actuator and CityU e-skin show feedback with sufficient richness and speed for practical use, and the prosthetic trials demonstrate feedback improving real task performance (object recognition, safer grip)[4][5]. These successes clearly exceed what previous “vibration-only” solutions could do, supporting a Level 4 PoC status for the overall technology.

Some aspects are even approaching Level 5: for example, HaptX's shipping product and competing efforts indicate that **well-capitalized actors are now developing production-grade prototypes** (in VR/AR haptics, at least)[6]. However, this ART is a *bundle of technologies* across different domains, and their maturity is uneven. **Sub-component breakdown:**

- **VR/AR wearable haptics: Level 5.** Advanced prototypes like HaptX G1 gloves (USA) and other haptic suits are in late-stage development with significant investment, targeting niche deployments. Big players (e.g. Meta Reality Labs, startups in Japan/Korea) are actively competing to refine these devices. The presence of a market-ready glove system[6] and rapid progress in actuator materials[11] and form-factors suggest that production prototypes exist and initial customers are receiving units – aligning with Level 5 criteria.
- **Prosthetic sensory feedback (medical/assistive): Level 3–4.** While the scientific feasibility is proven (restoring touch and even temperature in amputees[26]), the technology remains in clinical trial or lab prototype phase. No mass-produced sensory prosthesis is on the market yet; efforts are largely research-driven (e.g. EU and DARPA programs, academic spinoffs). Given that single-patient studies have shown success (a strong Level 3 demo) and small-scale trials are expanding, this sub-field is on the cusp of Level 4 (functional PoC with viability) but not yet at widespread commercial prototyping.
- **Industrial/robotic haptics (teleoperation, exoskeletons, training): Level 4.** Research prototypes have been integrated into real scenarios like robotic surgery simulators[5] and industrial training rigs, demonstrating clear benefits. Some startup products (force-feedback robot controllers, haptic training simulators) exist in pilot deployments. The technology meets functional needs and is plausibly cost-justified in

high-end applications, but it's not broadly adopted or produced at scale (no large commercial rollout yet, keeping it short of Level 5).

Given these variations, we average the maturity to **approximately a 4**. In essence, **the core capabilities of “haptic and multi-sensory feedback systems” are already demonstrated in working prototypes (Level 4)**. The **jump to Level 5** (early commercial and competitive phase) is underway in some areas (wearables for VR), but **not uniformly achieved across all applications**. To fully reach the next level, we would need to see more **converged progress**: multiple companies shipping robust products in this category, lower-cost manufacturing scaling up, and broader user adoption beyond pilot users. Evidence of this – such as competing haptic prosthetics entering the market, or lighter haptic suits moving from demo to product – is still emerging. Once the technology sees wider production financing and a growing customer base (e.g. consistent orders for haptic wearables, established supply chains for components), the score would advance. For now, the ART sits at **Level 4**: proven feasible with strong prototypes and initial real-world trials, and on the brink of broader commercialization pending further integration and cost reduction.

## ART 04.026 AI Understanding of Human Intent & Context

179. **ART extraction**

180. *Primary capability:* AI systems that infer a user’s underlying intent and situational context from rich, multi-modal behavioral cues, moving beyond literal commands to understand “what people mean.” These systems aim for more natural, human-like interactions by interpreting tone, gestures, facial expressions, gaze, posture, proximity, etc., in addition to spoken or typed commands.

181. *Key sub-components/variants:*

- **Multi-modal sensor inputs & fusion:** Aggregating data from microphones (speech/prosody), cameras (facial expressions, body language, gaze), wearables (physiological signals, motion), ambient IoT sensors, etc., and fusing them in real time to form a coherent context model.
- **Specialized inference modules:** e.g. gaze tracking and eye-contact detection, posture and gesture recognition, micro-expression and emotion detection (affective computing), and social signal processing (identifying engagement level, roles, turn-taking cues).
- **Situational context modeling:** Continuously maintaining a model of “who is present and doing what,” inferring likely goals, attention focus, and social dynamics (e.g. speaker vs. listener roles, group vs. individual context) from observed cues.
- **Adaptive response generation:** AI adjusts its interaction modality and timing based on context – choosing whether to respond via speech, visual display,

haptic feedback, or silently adjusting a setting – and tailoring its tone and behavior to user preferences, accessibility needs, and cultural/social norms (e.g. remaining silent in meetings, using formal vs. casual language, etc.).

- **Edge and cloud deployment:** Depending on latency, energy, and privacy needs, such context-understanding AI might run on-device using AI accelerators (comparable to high-end phone/AR hardware) for instant response, or offload to cloud services (with enterprise-level pricing) for more intensive analysis – or a hybrid of both.
- **Privacy and human override:** Built-in data privacy protections (on-device processing, data anonymization, etc.) and user controls are critical, given the sensitive nature of continuous monitoring. Users must be able to review, tweak, or override the AI's inferences and actions to ensure trust and alignment with human intentions.

182. *Maturity indicators/evidence:*

- **Research prototypes and demos:** Lab-proven systems combining multiple modalities (vision, audio, etc.) to interpret user intent in real time (e.g. an AR assistant that uses eye-gaze + pointing to resolve ambiguous commands). Evidence would include peer-reviewed studies demonstrating such prototypes in realistic tasks or user studies.
- **Benchmarks and accuracy gains:** Creation of multi-modal intent recognition benchmarks, and recent papers showing that these AI models outperform unimodal baselines (e.g. higher intent classification accuracy when combining speech and facial cues), indicating the scientific feasibility of inferring context/intent<sup>[1][2]</sup>.
- **Pilot deployments & partial features:** Early integration of context-aware features in commercial products. For example, laptops and smart displays now include human-presence sensors and gaze detection to auto-dim or wake screens, or voice assistants adding vision-based speaker recognition or “conversation mode” to handle multi-user environments. Such instances signal that industry is testing the waters with context-sensing capabilities.
- **Multiple actors & investment:** Large tech companies (Amazon, Google, Apple, Microsoft, etc.) and interdisciplinary research labs globally are actively pursuing “ambient” or context-aware AI for assistants, AR/VR, vehicles, and smart environments. Evidence of well-funded programs (e.g. DARPA's “Artificial Social Intelligence for Teams”) and corporate roadmaps/press releases about context-intelligent features demonstrates competition to develop robust production-grade systems.
- **Standards and ethics considerations:** The emergence of guidelines or debates around emotion AI and context inference (e.g. privacy standards, calls for regulation of affect recognition) also indicates that the technology is maturing enough to draw societal scrutiny – a sign that real deployments are on the horizon, albeit gated by ethical concerns.

183. **Evidence (10–20 recent, reliable sources)**

184. **A Survey on Multi-modal Intent Recognition: Recent Advances and New Frontiers –**  
*Zhihong Zhu et al. (Tencent Jarvis Lab & CUHK) – Peer-reviewed conference survey (Findings of*

EMNLP 2025) – **Nov 2025**. [2][3] A comprehensive survey of 60+ studies (2019–2024) on **multi-modal intent recognition (MIR)**, where AI combines text, audio (prosody), and visual cues (gestures, expressions) to infer user intent. It highlights that integrating diverse modalities enables a more *holistic interpretation of human intent* than text or speech alone, with rapid recent progress and even unified benchmarks/leaderboards now in place[2][3] – evidence that the research community has coalesced around this challenge and demonstrated substantial accuracy gains over unimodal systems.

185. **Deep Learning Approaches for Multimodal Intent Recognition: A Survey** – H. Zhang et al. – **Preprint (arXiv 2507.22934)**, supported by China National R&D Program – **July 2025**. [1][4] This article finds that fusing inputs from audio, text, vision (even gaze and physiological signals) has *significantly improved the accuracy of intent recognition in real-world scenarios*[1]. Advanced deep learning techniques (transformers for cross-modal fusion, etc.) let models leverage complementary information from each modality, yielding more robust understanding of user goals[1]. It also outlines remaining challenges – e.g. handling asynchronous or conflicting signals and modality mismatches – underscoring that **sensor fusion and context inference** are technically feasible but need further refinement for reliability[4].
186. **GazePointAR: A Context-Aware Multimodal Voice Assistant for Pronoun Disambiguation in Wearable AR** – Jaewook Lee et al. (Univ. of Washington & Univ. of Illinois) – **Peer-reviewed (CHI 2024)** – **May 2024**. [5][6] Demonstrates a fully functional **prototype voice assistant on AR glasses** that uses *eye-gaze + pointing gestures + conversation context* to interpret ambiguous user commands. For example, the user can look at an object and ask “What is **this**?” – the system replaces “this” by recognizing the gazed-at item, then answers appropriately[5]. In lab trials with 12 users, participants found these context-aware interactions more natural and human-like than today’s assistants[6]. This is a proof-of-concept that AI can infer intent (“what’s over there?”) from spatial context and nonverbal cues in real time, solving problems (pronoun resolution) that current commercial VAs cannot handle[7].
187. **Context-based Emotion Recognition: A Survey** – Rizwan Abbas et al. (Zhejiang Univ. & Westlake Univ.) – **Peer-reviewed journal (Neurocomputing)** – **Feb 2025**. [8][9] Reviews the fast-growing field of **affective computing with context**, showing that emotion recognition accuracy is greatly enhanced by incorporating context like body language, tone of voice, and situational cues rather than relying on facial expression alone. Deep learning advances in the last few years have enabled real-time emotion detection systems (e.g. detecting driver fatigue or retail customer sentiment on the fly)[9]. The survey stresses that emotions are culturally and socially influenced, so context-aware models are crucial for reliability[10]. This supports the ART’s feasibility in recognizing *emotional tone and engagement level* as part of understanding intent, while noting the need to adapt to individual and cultural variation.
188. **“Ambient intelligence” will accelerate advances in general AI** – Rohit Prasad (Head Scientist, Amazon Alexa) – **Industry research blog (Amazon Science)** – **Jan 2023**. [11][12] Amazon’s Alexa team articulates a vision of **ambient AI** assistants that proactively understand users by combining **multisensory inputs** and **affect recognition**. They highlight two critical capabilities: (1) *processing multiple sensor streams* (mics, cameras, even ultrasound) and fusing them to infer the user’s goals, and (2) *interaction skills* including conversational fluidity and recognizing/responding to human emotions[11]. The blog notes that Alexa is evolving to become *more natural, personalized, and proactive* – e.g. anticipating needs via awareness of the shared environment and acting on the user’s behalf when appropriate[12]. This indicates major industry investment toward AI that continuously models context and intent in line with the ART description.

189. **STMicroelectronics Human Presence Detection for Laptops** – *STMicroelectronics (press release)* – **Vendor technical announcement** – **June 2025**. [13][14] European chipmaker STMicro introduced an advanced **Human Presence Detection (HPD)** module for PCs, combining a time-of-flight ranging sensor with on-device AI algorithms. This module, already designed into >260 laptop models, lets computers “sense” if a user is present or approaching, enabling *hands-free logins (Windows Hello)*, auto-lock when you walk away, and ~20% daily power savings by intelligently managing sleep states[13][14]. The solution improves privacy (e.g. alerting if someone is shoulder-surfing) and demonstrates **ambient context awareness** in commercial hardware. The broad adoption of these sensors shows that real-time multimodal sensing (in this case, detecting a human via depth sensor + AI) is *already deployed at scale*, a stepping stone toward more complex intent-aware interfaces.
190. **Eye-Tracking and Gaze Estimation for AR/VR: A Review** – *Liwan Lin et al. (Xiamen University)* – **Peer-reviewed journal (Electronics)** – **Aug 2025**. [15] Surveys recent AR/VR headsets’ eye-tracking capabilities and notes they can provide *real-time insights into user attention and intent*, enabling systems to dynamically adapt content or interface based on where you’re looking[15]. For example, the Apple Vision Pro and Meta Quest Pro use eye-gaze as a primary input modality. This reflects a tangible component of the ART: devices that **infer user intent (what the user is focusing on)** from gaze and adjust their behavior accordingly. Such **gaze-based intent inference** is now reliable enough for consumer use, lending plausibility to AI that monitors subtler cues like eye contact and attention in broader contexts.
191. **Toward Socially-Aware LLMs: Multimodal Approaches to Human Behavior Understanding** – *Ahn et al. (Univ. of Michigan, Microsoft Research, et al.)* – **Preprint (arXiv 2510.23947)** – **Oct 2025**. [16][17] Reviews 176 studies on AI systems that combine large language models with visual/audio perception to analyze human social behavior. It finds AI is being applied to **interpret complex social contexts** – e.g. models that assess student engagement from classroom videos, or that infer teamwork dynamics (roles, strategies) from multi-person interactions[16]. The authors define core capabilities for “socially intelligent” AI aligned with this ART: the ability to interpret multi-modal social cues, reason about multi-party dynamics, and infer individuals’ mental states and intentions[17]. The existence of this large body of work and its interdisciplinary nature (AI, HCI, education, etc.) shows a concerted effort to endow machines with **human-level social context understanding**, supporting both the plausibility and the recognized value of such technology.
192. **Qualcomm on On-Device AI for Contextual Experiences** – *Qualcomm Technologies* – **Industry whitepaper** – **2024**. [18][19] Qualcomm outlines its roadmap for **context-aware AI agents running on consumer devices**. It envisions personal AI that can “predict user needs and proactively execute tasks” by continuously learning a user’s preferences and context locally (via a personal knowledge graph)[18]. Crucially, they note this will make *AI the primary UI*, with natural language, image, video, and gesture inputs replacing today’s explicit interfaces[19]. The whitepaper points out that efficient on-device AI processing allows such agents to operate *securely and continuously without cloud dependency*, aligning with the ART’s emphasis on real-time inference and privacy. Qualcomm’s investment in multi-modal AI hardware (smartphone SoCs, AR/VR platforms, automotive “digital chassis” for intelligent cockpits) is strong evidence of industry momentum toward **ubiquitous context-aware AI** in the next generation of devices.
193. **DARPA ASIST (Artificial Social Intelligence for Successful Teams)** – *U.S. DARPA Program (I2O)* – **Government research program** – **2019–2023**. [20][21] The DARPA ASIST program was devoted to developing AI agents with **Theory of Mind and situational awareness** to work in teams with humans. Its goal was to demonstrate machine “social skills” like inferring human teammates’ goals and knowledge state, predicting their needs, and taking *context-*

*aware helpful actions* during missions[20]. The program description emphasizes that AI has made little progress in understanding the “most important part of its environment: humans,” and ASIST sought to fill that gap by giving AI the ability to interpret context and maintain shared mental models with people[21][20]. The existence of this multi-year, completed project (with multiple research teams and testbeds) signifies both the **feasibility and strategic importance** of AI that deeply understands human intent and context, at least in constrained team scenarios – a strong precursor toward the broader ART vision.

#### 194. **Maturity score (1–7) and reasoning**

##### **Final Score: 4 (Proof-of-Concept demonstrated)**

**A. Justification of score:** The evidence places “AI understanding of human intent & context” at a **transitional stage between lab prototypes and early practical implementations**, corresponding to **Level 4**. Multiple **proof-of-concept systems** have been *scientifically demonstrated* that fulfill key functionality of the ART: for example, the CHI 2024 demo of a gaze+gesture-driven assistant shows that machines *can* interpret non-verbal context to disambiguate user intent in real time[5]. Likewise, multimodal AI models now reliably outperform purely text- or audio-based systems, proving the core principle (fusing diverse human signals) and solving previously blocking problems of intent recognition accuracy[1]. These successes go beyond a Level 3 “lab prototype” because they tackle real-world complexity (e.g. handling pronouns in unconstrained speech, or detecting emotion across different settings) and demonstrate **viability for practical use** (the AR assistant was tested with naive users, and industry benchmarks show significant gains)[6][1]. We also see **commercial readiness signals**: parts of this technology are already **integrated into products** (e.g. laptops with presence-sensing AI, smart speakers using vision for multi-speaker context[22]), indicating that some components meet production requirements in robustness and cost. The involvement of big tech companies and well-funded projects (Amazon’s ambient Alexa vision, Qualcomm’s on-device AI, DARPA ASIST, etc.) means progress is rapid and focused on scaling up – a hallmark of the PoC-to-product transition (Level 4–5).

**B. Why not a higher score?** The **holistic, generalized version** of this ART (an AI that fluidly understands any user’s intent, in any context, and adapts like a human assistant) is *not yet a finished product* or an industry standard – it remains an active R&D frontier. We do **not** have Level 5 evidence of multiple companies selling directly competing “intent-aware AI” products or a fully finished production prototype. Instead, we see *fragmented partial implementations*: one product might detect faces and gaze, another detects tone, but they are not unified into a single system that consistently handles the full spectrum of human context. Key challenges identified in research – such as **cultural/generalizability issues, multimodal data conflicts, and privacy/ethics constraints**[4][10] – are still being worked through before wide deployment. Moreover, public **backlash over emotion recognition** (e.g. Zoom’s now-paused plan for video call “emotion AI”) shows that social acceptance and policy frameworks lag behind, which currently slows commercialization. Thus, the technology as a whole hasn’t reached Level 5’s “finishing phase of a production prototype” or Level 6’s “broad market adoption” – no virtual assistant yet offers the full intent-and-context awareness envisioned (we see *prototypes* and *roadmaps* instead of consumer-ready, fully trusted solutions).

**C. Sub-component breakdown:** This ART comprises several interdependent tech strands with **uneven maturity**:

- **Multi-modal sensing & fusion:** *Maturity ~5.* Sensors (cameras, mics, depth, wearables) and edge AI chips are already in devices worldwide, and frameworks for sensor fusion exist. For instance, human-presence detection and gaze tracking are shipping in laptops and AR/VR headsets[13][15], and cloud APIs for sentiment or vision analysis are offered by multiple vendors. There is active competition here (sensor/AI hardware from Apple, Qualcomm, STMicro, etc.), suggesting an approaching **production scale** for the sensing layer. However, fusion at scale (combining *all* modalities robustly) still faces integration challenges (synchronization, power management).
- **Intent inference algorithms:** *Maturity ~3–4.* Academia and corporate labs have prototyped the **context interpretation algorithms** – e.g. fusion models that beat baselines[1], or assistants like GazePointAR[5] – demonstrating the concept works. Yet, these are early-stage implementations (often task-specific or in controlled studies). They meet functionality requirements (they clearly exceed what previous single-modal systems could do, fulfilling the rubric for Level 4), but **reliability, bias and edge cases** remain concerns. We haven’t seen a *general* intent-understanding AI handle the messiness of everyday life outside of pilot tests. Further training on larger datasets and solving open research problems are needed to reach consistent real-world performance (transition to Level 5/6).
- **Adaptive response & HCI integration:** *Maturity ~4.* There are proofs that adaptive, context-aware responses improve user experience (users in studies found it more natural[6]). Modern HCI research and some voice assistants have started implementing adaptive behaviors (e.g. Alexa’s “Conversation Mode” uses vision to decide if it’s being addressed[22]). Still, the *full* repertoire of modality switching and social-norm adherence (as described in ART) is experimental. No off-the-shelf assistant yet, for example, silently switches your phone to vibrate because it “knows” you’re in a meeting – but the building blocks (calendar context, audio scene analysis for meeting sounds, etc.) are emerging.
- **Privacy, personalization, override mechanisms:** *Maturity ~3.* Technically, solutions like federated learning, on-device processing, and user dashboards for data are known, but **trust and policy frameworks** are lagging. The need for these safeguards is recognized (research frequently cites them, and standards bodies are beginning discussions), but their implementation will likely come as the tech nears productization. Right now this aspect is more a requirement than a delivered feature set, keeping the overall maturity moderated.

Considering these sub-components together, the **overall ART** functionality – an AI that seamlessly understands intent and context – is roughly an **average of the above**, which lands around **Level 4**. Some pieces (sensors, hardware) are ahead, indicating the platform is ready, and there is **clear recent progress** pushing the tech beyond proof-of-concept (justifying higher than Level 3). However, the **ultimate integration and refinement** needed for a polished, widely-deployed product is still in progress. Therefore, Level 4 is appropriate: the concept has been proven viable in prototypes and even partial real-world deployments, but further development and convergence of sub-technologies are required to reach full commercial realization.

## ART 04.027 Brain-to-Brain Interfaces

### 195. ART extraction

**A) Primary capability** – Enabling direct exchange of brain activity patterns between individuals as a new communication channel. This would vastly increase communication bandwidth and reduce ambiguity by transmitting perceptions, intentions, or mental states directly, rather than through speech or text. It promises novel forms of coordination, letting people “share mindsets” for enhanced collaboration or situational awareness.

### **B) Key sub-components/variants –**

- **Brain activity sensing:** Non-invasive or minimally invasive neural sensors (e.g. EEG, MEG, fNIRS, or high-density implants) to record the sender’s brain signals associated with specific thoughts, intentions, or sensory experiences.

- **Decoding algorithms:** Adaptive machine learning models trained per user to translate raw neural signals into a *shareable digital representation* of the sender’s intended message or

state (while filtering noise or irrelevant activity).

- **Communication link:** A secure digital interface (wired or wireless) to transmit the encoded neural information between brains. This could be a direct device-to-device link or a network if multiple brains (“BrainNet”).

- **Brain stimulation/output:** Targeted neural stimulation or feedback at the receiver’s side to *write* information into the brain. This might use transcranial magnetic stimulation (TMS), focused ultrasound (tFUS), transcranial electrical stimulation (tES), optogenetics (in animals or with genetic mods), or implanted microstimulators to induce structured perceptions, cues, or biases rather than fully formed thoughts.

- **Multi-brain configurations:** Interfaces can be unidirectional (one sender, one receiver) or bidirectional (two-way exchange), and may scale to networks (multiple senders and receivers). Early systems are mostly one-to-one; future “brain networks” could allow **many-to-many** information sharing[1][2].

- **User controls & consent:** Interface software to manage channels and permissions – users choose *what type* and *how much* information to share, maintaining privacy and safety. This includes calibration routines for each user and safety interlocks to prevent unintended influence.

**C) Maturity indicators** – We would look for evidence of **laboratory proofs-of-concept** where information is successfully sent from one brain to another (e.g. solving tasks via brain-to-brain link), and demonstrations moving beyond trivial signals (more than a simple binary “yes/no”). Key indicators include: **bidirectional prototypes** (two people exchanging information simultaneously), **multi-person experiments** (networks of 3+ brains)[3][4], and **improved bandwidth** (transmitting more complex stimuli or faster signals). Progress toward practical use would be signaled by integrated BBI “**headset**” **systems** rather than ad-hoc lab setups – for example, non-invasive BBI rigs achieving real-time operation. Other signs include **field trials or clinical tests** (e.g. using BBI to aid a disabled patient with a therapist’s help), and **multiple independent groups or companies** heavily investing in BBI-related technology (a competitive R&D environment). Evidence of **safety and ethics frameworks** being discussed (military or healthcare contexts) also suggests the concept is taken seriously enough to prepare for deployment. Finally, early **commercial prototypes or large funding rounds** for BBI-specific startups (or BCI companies explicitly aiming at brain-to-brain communication) would indicate maturity toward viable products.

196. **Evidence (10–20 recent, reliable sources)**

***Brain-to-brain direct coupling demonstrated (human experiment, 2025): Matani et al., Brain Research, Jan 2026 – Peer-reviewed paper.\**** Publication date: **01/2026**.

Findings: **Discovered a form of “volume current coupling” that electrically links two human brains’ signals directly. Two people were connected via transcranial electrodes that allowed leakage currents from one brain to influence the other. When isolated subjects were linked this way, one person’s brain activity induced measurable bias in the other’s behavior[5][6].** **Significance:** It shows a direct brain-to-brain channel affecting cognition without any computer decoding\*\*, suggesting new physical mechanisms for BBI. This lab demo confirms the plausibility of brain-to-brain information transfer using purely electrical coupling, and that such coupling can alter behavior (albeit in a limited way), underscoring the scientific feasibility of BBIs.

**Systematic review of BBI research (15 studies) – field is nascent: Nam et al., Frontiers in Neurorobotics, May 2021 – Peer-reviewed systematic review.\*** Publication date: 05/2021. Findings: Reviewed all BBI experiments up to 2020 (15 studies total). Most were unidirectional and used a BCI (EEG) on a sender plus a CBI (usually TMS) on a receiver[11]. A common approach was evoking *phosphenes* (flashes in vision) via TMS based on another person's EEG, enabling binary signals (yes/no)[1][7]. Notably, 86% of studies were one-sender/one-receiver; only ~13% tried more complex setups[7]. No standard method for stimulation has emerged – groups variously tried TMS, tDCS, ultrasound, optogenetics, etc. Bidirectional BBI in humans has been very rare (only one early study in 2015 used a partial two-way loop)[1][8]. **Significance:** This shows BBIs had passed the initial proof-of-concept stage by 2020 but remained extremely limited in capability (mostly transmitting one-bit signals or simple triggers). It establishes a baseline: the concept works in principle (ruling out Level 1), but by 2020 BBIs were still laboratory curiosities requiring significant setup and calibration, with no multi-channel high-bandwidth communication yet\*\*. It also highlights key hurdles like inconsistent neurostimulation methods and need for more than 1:1 links – challenges that subsequent research is now tackling.

**Multi-person BBI “BrainNet” and collaborative problem solving: (Jiang et al., 2019) Nature Scientific Reports – Peer-reviewed experimental paper.\*** Publication: 11/2019. Findings: Demonstrated *BrainNet*, the first multi-person, non-invasive BBI for group collaboration[9]. Three people (two “Senders” with EEG caps and one “Receiver” with EEG+TMS) jointly played a Tetris-like game by exchanging binary signals via brain-to-brain links[9][10]. Senders saw the game and decided whether to rotate a piece, encoding “Yes/No” by focusing or not focusing on a flashing light (EEG steady-state response). The Receiver, blind to the game, received the senders' decisions through TMS-induced phosphenes and integrated this input to make moves[11]. Over repeated trials, the group achieved task performance above random chance. **Significance:** Although slightly older (2019), this milestone experiment showed feasibility of a network BBI (2→1) and that brains can collaborate on a task using a direct neural link. It proved scaling beyond one-to-one is possible and that a BBI can do more than send a single bit in isolation – here a team used it to solve a visuo-motor task. BrainNet's success provided a template for future BBI systems, moving the field closer to Level 3 maturity (lab prototype with key functionality) by showing multiple users exchanging meaningful information\*\*[9][10]. It also flagged the high computational demands of real-time decoding and the intensive user training needed, which current research is working to streamline.

**DARPA “MOANA” project – towards non-invasive, high-speed BBI headsets: Robinson (Rice Univ.) et al., DARPA N3 Program – U.S. Defense research project (press release)\*.** Date: 01/2021 (follow-up funding awarded). Details: The MOANA project (“Magnetic, Optical and Acoustic Neural Access”) received \$8M from DARPA to build a dual-function wireless headset for brain-to-brain communication[12][13]. The goal is a minimally invasive, bidirectional BBI: it uses infrared light for reading brain activity and magnetic fields (with injected magnetic nanoparticles) for writing into the brain, targeting <50 ms latency links[14][15]. In initial tests, the team showed they could optically detect neural signals through a skull and precisely stimulate neurons in vitro via magnetothermal effects[15]. Phase 1 solved key physics challenges (photon collection through skull, magnetic nanoparticle heating control). Now in Phase 2, 16 partner labs are integrating

these into a rodent BBI prototype, with a goal of human testing in ~2023[16][14].

**Significance:** MOANA represents a well-funded, multi-disciplinary push to overcome the main technical blockers: it's developing high-bandwidth non-surgical I/O (optical diffuse tomography and magnetogenetics) and modular wearable designs[17][18]. Notably, DARPA set specs to rival implant performance (read/write 16+ channels in 16 mm<sup>3</sup> of brain at <50 ms[19][20]). By Phase 3 they aim to demonstrate a closed-loop *human* BBI link[21]. This indicates the technology is transitioning from isolated academic demos to coordinated prototype development\*\*, a hallmark of Level 3 maturity. The involvement of DARPA and teams at Battelle, Carnegie Mellon, Johns Hopkins APL, PARC, Teledyne, etc. (in parallel N3 projects)[22] underscores that multiple well-resourced actors see promise in high-performance brain interfaces, accelerating progress toward practical BBIs.

**EU “BrainBIT” project – all-optical BBI for rehab (ERC grant): Pavone et al. (Univ. of Florence), BrainBIT project report (CORDIS) – Authoritative research project report.\*** Project period: 12/2016 – 05/2022. Results: **Developed advanced** two-photon optogenetics technology to read and write neural activity across brains with high resolution[23][24]. In zebrafish larvae, they achieved whole-brain functional imaging while simultaneously stimulating specific neurons, allowing them to capture an animal's neural pattern for a behavior and *induce that pattern in another animal*[25][26]. They demonstrated transferring a neural signature associated with efficient motor recovery from one mouse to another: mice with better post-stroke rehabilitation were used as “donors” of neural activity templates, which were optogenetically replayed in other mice to improve their recovery[25][27]. The project overcame challenges in separating optical read vs write signals by shifting to two-photon excitation (different wavelengths)[28], and built a “pump-and-probe” framework for cross-brain stimulation. **Significance:** This is a successful in-vivo BBI demonstration in mammals for a therapeutic outcome (*enhancing stroke rehab in mice*) using no electrodes – purely light-based. Achieving whole-brain neural transfer with spatiotemporal precision was a major technical hurdle, and BrainBIT's innovations (e.g. two-photon excitation, fast volumetric imaging) show plausibility for high-fidelity BBIs[24][29]. While still preclinical, it points to BBIs addressing real-world bottlenecks (rehabilitation efficacy) and illustrates international progress (EU investment) alongside US efforts. It also highlights that later-generation BBIs may initially appear as “specialized installations” (since current two-photon setups are bulky and costly), with a roadmap to miniaturization.

**First bidirectional human BBI in the works (NSF project): NIU Press Release (C.S. Nam), Feb 2025 – University news (NSF grant announcement).\*** Date: 02/2025. Details: Reports a new \$600k NSF-funded project led by Prof. Chang Soo Nam (NIU) and Dr. Xiaoning Jiang (NC State) specifically to develop a two-way brain-to-brain interface in humans[30][31]. The team will combine noninvasive *brain-reading* (EEG, MEG or fNIRS) with *brain stimulation* (in particular focused ultrasound, tFUS) to allow two participants to send and receive information *simultaneously*[32][33]. They note that since 2013, basic one-way BBI has been shown in labs, but no fully bidirectional BBI exists yet[34][35]. The goal is to pioneer the first true two-way BBI system, where each person's intentions can be encoded and delivered to the other in real time. Envisioned applications include doctor-patient communication for locked-in patients, enhanced stroke rehabilitation, and rapid idea sharing between healthy users[36][31]. **Significance:** This grant indicates that mainstream research funding agencies are now backing BBI development. The emphasis on

**tfUS is notable: ultrasound offers deep, focused stimulation with no implants, aligning with the ART's noninvasive aspiration.** If successful, this project would mark a jump to Level 4 (proof-of-concept): *a functional prototype meeting basic requirements for real-time, two-way operation in humans.* The fact that achieving bidirectionality is a stated milestone suggests current BBIs have been constrained (mostly one-way), and hitting this target would resolve a “previously-blocking” limitation. This effort, alongside others, shows clear recent momentum to move BBIs from isolated one-direction demos to robust interactive systems.

**High-density wireless brain implant boosts I/O bandwidth: Shepard & Tolias et al., Nature Electronics (press via Columbia Engineering), Dec 2025 – Peer-reviewed research (neural engineering).\*** Publication date: 12/2025. Breakthrough: **Unveiled an ultrathin, paper-like brain implant (“BISC”) with 65,536 electrodes and 16,384 micro-stimulators on a single CMOS chip[37], enabling high-bandwidth wireless read/write to the cortex[38][39].** Inserted under the skull (minimally invasive ECoG), it streams brain signals at up to 100 Mbps (over WiFi-like UWB) and supports real-time AI decoding of complex movements, speech and visual intent[40][41]. Initial clinical tests showed the device can be implanted through a small skull opening and remain stable, recording rich neural data[42]. Its integrated design (all components on one 3×3 mm chip) drastically reduces size and power requirements versus traditional BCIs[37][43]. **Significance:** While not a BBI itself, this represents state-of-the-art in brain interface hardware, attacking the “fidelity of sensing and stimulation” bottleneck cited in the ART description. BBI feasibility depends on such high-resolution, real-time interfaces. BISC's success suggests that transmitting *vast amounts of neural information* is becoming technically viable[41][44]. For BBIs, one could imagine two BISC implants (one in each person) linking via a wireless network to exchange thousands of channels of neural data – a scenario far beyond today's few-bit EEG/TMS links. In terms of maturity, this **demonstrates that** critical sub-systems (BCI and CBI)\*\* are nearing commercial-grade performance (the device even received NIH funding for epilepsy therapy[45]). Thus, one major barrier to practical BBIs – the lack of a high-bandwidth “neural modem” – is being addressed, paving the way for future BBI prototypes that meet the latency and throughput demands for real use.

**Dual-brain stimulation enhances cooperation via neural synchrony: Zheng & Lu, Neurolmage, Aug 2025 – Peer-reviewed experimental paper.\*** Finding: **Applied** simultaneous transcranial direct current stimulation (tDCS) to two people **during a Prisoner's Dilemma game, aiming to synchronize a specific brain region (right temporoparietal junction) involved in social cognition[46][47].** The study with 81 pairs showed that **active dual-brain stimulation** significantly increased inter-personal brainwave synchrony (measured by hyperscanned EEG/fNIRS) compared to sham or one-sided stimulation[48][47]. Crucially, pairs with enhanced neural synchrony adopted more cooperative strategies and earned higher mutual rewards in the game[49][47]. The effect was causal: turning the synced stimulation on and off led to corresponding changes in brain synchrony and cooperation levels[47][50]. **Significance:** This **demonstrates a rudimentary BBI use-case:** modulating two brains together to improve shared outcomes. Instead of transmitting an explicit message, the interface biased both participants toward a “team mindset” (via induced brain synchrony), which is one envisioned mode of BBI (sharing biases/attention rather than fully formed thoughts). The result validates that altering brain states in concert can meaningfully change behavior in

**a social task – essentially** augmenting human teamwork via neurotechnology. *It speaks to plausibility (brains can be externally aligned for better coordination) and hints at near-term applications like training or therapy: e.g. boosting therapist-patient rapport or keeping pilots in sync. As an experimental milestone, it goes beyond one-way information transfer and into shared cognitive state management, which is a key value proposition of BBIs in the ART description (adapting workflows around collective attention/fatigue).*

**Big industry investment in noninvasive BBI tech (ultrasound-based): Mullin, Wired, Jan 2026 – Tech journalism (factual report).**\* Context: **Reports on Merge Labs, a startup co-founded by OpenAI’s CEO Sam Altman, emerging from stealth with \$252M in funding to build brain-computer interfaces that use ultrasound for both reading and writing brain activity[51][52]. Merge’s approach foresees no surgical implants – instead, using gene-delivered molecules and focused ultrasound to noninvasively interface with neurons[53][54].** OpenAI’s involvement suggests the goal of integrating AI with high-bandwidth brain input/output, aligning with Altman’s “merge” concept of human-AI hybrid cognition[55]. The article notes that while companies like Neuralink (implanted BCIs) have raised >\$1B, Merge aims for a wearable, mass-accessible neural interface, and that other startups (e.g. Synchron, Paradromics) are also heavily funded in this space[52][56]. **Significance:** This is strong evidence of a *rapidly maturing ecosystem* around brain interfaces, which BBIs will directly benefit from. The fact that a quarter-billion dollars is being poured into noninvasive read/write modalities shows that key enablers for BBIs (like safe high-throughput neural links) are attracting major investment and talent\*. *Although Merge is initially focused on brain-to-computer links, the technologies (ultrasound neuromodulation, “neural foundation models” for decoding brain signals[57]) are exactly what a future BBI needs. This competitive landscape – OpenAI, Neuralink, academic spinoffs – indicates a Level 3–4 environment for BCI, which in turn propels BBI readiness. In short, multiple well-capitalized actors are racing to perfect noninvasive neural I/O, bringing BBIs much closer to reality. (Notably, Merge’s vision statement explicitly mentions ultimately achieving “broadly accessible” brain interfaces that blur humans and AI[55], essentially the long-term BBI ambition).*

### 1. Maturity score (1–7) and reasoning

#### Proposed Score: 3 (Laboratory prototype demonstrated)

**A) Justification – Brain-to-brain interfaces** have decisively moved past theoretical speculation (Level 1) and initial feasibility tests (Level 2) into the realm of working lab prototypes, but they have **not yet achieved a proof-of-concept that meets practical deployment criteria**. The evidence shows multiple **independent demonstrations of core functionality** – for example, transmitting information from one human brain to another to solve tasks[9][11], or linking animals to share motor or sensory states[25][27]. These experiments prove the fundamental *operating principle*: that neural signals can be captured, encoded, sent, and meaningfully decoded into another brain (ruling out Levels 1 and 2). Additionally, key previously-blocking problems have seen progress, such as:

- **Multi-node communication:** Going from one-to-one to multi-person networks (e.g. BrainNet’s 3-person BBI[9][10]) solved a conceptual hurdle and showed BBIs can scale beyond a single channel.
- **Improved I/O resolution:** Projects like MOANA and BISC have achieved orders-of-magnitude better neural reading and writing capability (milliseconds latency,  $\sim 10^4$ – $10^5$

channels)[18][37], addressing the fidelity bottleneck that once limited BBIs to sending a yes/no signal.

- **Noninvasive bidirectionality (in progress):** Efforts funded by DARPA and NSF are explicitly targeting two-way communication without surgery[33][21] – a milestone not yet reached but clearly in sight, which would remove one of the last “show-stoppers” for a convincing PoC.

With these advances, we have **laboratory prototypes that achieve necessary functionality**: for instance, the dual-brain tDCS study (2025) demonstrated that a BBI can actively enhance cooperation between people by syncing their neural activity[49][47] – directly showing a benefit unattainable by conventional means (you cannot induce that effect with normal communication). That addresses the ART’s “value-creation” claim on a small scale. Similarly, the rodent optical BBI (2020) achieved rapid info transfer for precise locomotor control[58][59], proving BBIs can surpass reflex-speed communication. These are **qualitatively new capabilities**, indicative of Level 3.

However, **evidence for Level 4 is not yet present**. A Level 4 PoC means a functional prototype that meets *real-world commercialization requirements* in reliability, integration, and clear advantage. What’s missing is demonstrated *robustness and scaling*: current BBI setups require heavy calibration, controlled lab settings, and often bulky equipment (e.g. MRI or optical rigs, tethers to PCs). There is **no BBI system yet that one could deploy in a practical scenario** (say, two operators in the field silently coordinating by BBI). Security, privacy, and regulatory aspects remain unproven at prototype level as well. In short, **no BBI has met the bar of being “viable for production” or clearly superior to existing solutions**. For example, the information rates achieved so far are still far below what simple speech or text can convey – a BrainNet game or yes/no question via BBI is orders of magnitude slower than speaking in person. Thus, while rapid progress is evident, BBIs remain in the experimental stage, not the product stage. The recent surge in funding and multi-group R&D (DARPA, EU, startups) suggests we are on the cusp of more integrated demonstrations (transitioning toward Level 4), but those results are just emerging (e.g. the first bidirectional human BBI is *planned*[35], not completed; initial human tests for MOANA are proposed[16], not yet reported). The **strongest evidence** (like multi-person BBI and high-density neural interfaces) *rules out* Level 2 definitively – we’re beyond isolated curiosity tests. Yet the **lack of any deployed prototypes or competitive commercial products** rules out Levels 5–7, and the absence of a polished, end-to-end working system at human “real-life” scale means Level 4 is not fully met.

**B) Evidence mapping to rubric** – Level 3 is characterized by a lab prototype showing necessary functionality with a key problem solved, even if cost/durability issues remain. We have:

- **Necessary functionality achieved:** We have seen **successful brain-to-brain information transfer** (binary signals in humans[9], visual pattern sharing in animals[58], and even induced cooperative behavior[49]). This indicates BBIs *can* do what was previously only hypothetical (direct neural communication).
- **Previously blocking problem solved:** Early on, it was unclear if noninvasive BBI was even possible. Now, between BrainNet and MOANA’s work, they’ve solved issues like *synchronous EEG-TMS control* and *through-skull optical signaling*[60][15]. Another

blocker – extremely low bandwidth – is being overcome by new hardware (e.g. BISC’s 100 Mbps link[41]). These achievements were essential steps toward viability.

- **Production issues remain:** Indeed, current systems are far from portable or affordable. For example, BrainBIT’s 2-photon microscope is not something you’d find outside a lab, and even the upcoming MOANA headset will initially be complex and costly (comparable to an advanced medical device). There is no evidence of cost reduction or mass manufacturability yet – pointing to Level 3 (prototype) rather than 4 (product-ready PoC).

**C) Sub-component maturity (bundle analysis)** – The ART combines multiple technologies (neural sensing, decoding AI, wireless link, neural stimulation). These pieces have somewhat different maturity levels today:

- *Non-invasive neural sensing (EEG, fNIRS, etc.):* Fairly mature (used clinically and in consumer EEG headsets), but limited in resolution. Cutting-edge sensing like high-density EEG or emerging tech (optical, MEG) is improving. Overall ~Level 4 for basic EEG (commodity devices exist), but only ~Level 3 for the **new high-res optical/ultrasound methods** being developed (shown in lab, not yet general-use).
- *Neural decoding algorithms:* Machine learning for BCIs is an active area – e.g. AI decoding of speech from brain signals just hit practical demos in 2023. For BBIs, personalized decoding is essential. This sub-component is around Level 3–4: proven in lab (AI decoding enables real-time BCI control in labs[61]) but not a finalized product (needs more training data and generalization).
- *Neural stimulation outputs:* TMS/tES are well established in research (Level 4 in sense they are used in clinics for other purposes), but **precise information injection** is nascent. Focused ultrasound (tFUS) and magnetogenetics have shown promise in lab animals[62][63] but are at Level 2–3 experimentally. Invasive stimulators (microelectrodes) are at Level 4 for medical implants (e.g. DBS), but using them for BBI is Level 2 (no dual implant BBI done yet).
- *Secure wireless communication link:* This is relatively mature (wireless EEG packs, Bluetooth etc., Level 5), but ultra-low-latency, high-bandwidth brain links are just reaching prototypes (the BISC UWB link – Level 3). However, standard networking tech can be leveraged, so we can consider this piece not a limiting factor now.

Because these sub-components must work *together* for a BBI, the overall system maturity is constrained by the least mature elements – notably, *neurostim output and integration*. In practice, today’s BBIs function, but with low fidelity and intensive setup, which places the **overall system at Level 3**. We therefore aggregate to **Level 3**, reflecting that **the concept is proven with working prototypes in research settings, but significant development is needed to approach a usable, scalable product**.

**What’s needed to reach Level 4?** We’d expect in the next few years a demonstration of a **full-loop BBI in humans** where two people achieve a complex task *better or faster* via the BBI than by other means, using a relatively self-contained device. For instance, a bidirectional BBI that enables a locked-in patient and a healthy user to communicate basic thoughts (on the order of a few bits per second) reliably would constitute a Level 4 PoC – it would show clear benefit over the status quo (no communication or slow assistive tech) and be on a path to practical deployment. To get there, ongoing work must improve the information rate (so that

meaningful chunks of data – not just binary – can be exchanged) and reliability/latency of the system, as well as ensure safety and consent mechanisms are foolproof. The evidence suggests those advances are underway (with AI decoding, better hardware, and serious funding), but until they coalesce into an integrated demonstration, BBI remains at **Maturity 3**.

## ART 04.028 Memory Prostheses

### 2. ART extraction

3. **Primary capability:** Implantable “memory prosthesis” devices that interface with the brain’s memory circuits to **restore or enhance memory function**. These implants would sense neural activity during memory formation and **record the neural patterns**, then later **replay or stimulate those patterns** to reinforce recall or replace missing signals, effectively **substituting for damaged memory-encoding processes**.

### 4. Key sub-components/variants:

- *Neural interface hardware:* Miniaturized, implantable electrode arrays placed in memory-related brain regions (e.g. hippocampus) to **record and stimulate neural signals**, designed to match the brain’s circuit layout and dynamics.
- *Sensing & decoding algorithms:* On-board or external **signal processing models (e.g. “memory decoding models”)** that detect when new memories are being formed by analyzing multi-site neural activity patterns, and that predict the appropriate output pattern for memory storage[1][2].
- *Data storage & processing:* Embedded memory and controllers to **store neural activity patterns** (in compressed, anonymized form) and run real-time computations (possibly AI or model-based) to decide when and how to stimulate.
- *Stimulation/replay system:* Electrical stimulators to **inject recorded patterns back into the brain** (e.g. into downstream hippocampal neurons) at opportune moments, subtly reinforcing weak memories or **“replaying” memory codes** to enable recall that would otherwise fail.
- *External interface & personalization:* Secure wireless interfaces for **configuration and updates**, allowing clinicians to adjust parameters and download software. Over time the system would **learn the individual’s unique neural signatures of memory success** and personalize the stimulation patterns. Multiple implants could be networked together and linked to external devices for synchronization and data telemetry.

- *Power and safety constraints:* Low-power operation (microwatt–milliwatt range) with careful thermal management to avoid tissue heating, and **biocompatible packaging** for long-term implantation. The device must be **fully implanted (no transcutaneous leads)** and inductively powered or with rechargeable batteries, similar to a cochlear implant or deep-brain stimulator. Heat dissipation, battery life, and **fault tolerance (to avoid dangerous failures)** are critical design factors.
- *Surgical and cost considerations:* Requires neurosurgical implantation (initially as complex as epilepsy or Parkinson’s implants). Early devices would be expensive (akin to major surgery plus specialized hardware), but with scale could approach costs of common implants (e.g. cochlear or cardiac devices).

5. **Maturity indicators (evidence):**

- *Laboratory demonstrations:* Peer-reviewed studies showing **proof-of-concept in animals or humans**, e.g. recording hippocampal activity and electrically improving memory performance in memory-impaired subjects. Evidence of memory retention improvements or restored recall in controlled tasks would indicate plausibility.
- *Prototype devices:* Development of **implantable multi-channel neural prosthesis prototypes** (wireless, closed-loop systems) tested in vivo. Key metrics include number of channels (e.g. tens of electrodes), ability to record and stimulate simultaneously, stability over time, and safe operation. Large-animal studies or first-in-human trials of such prototypes would mark progress toward practical use.
- *Clinical trials and consortia:* Initiation of **clinical trials** (or advanced pilot studies) in patients with memory loss (e.g. Alzheimer’s, TBI, epilepsy) using a memory prosthesis system. Also, **major funded programs** (e.g. DARPA’s Restoring Active Memory, EU’s ERC projects) or industry efforts (startups, medtech companies) competing in this space show momentum.
- *Efficacy beyond existing methods:* Evidence that this approach can **significantly improve memory recall or storage compared to no intervention or traditional stimulation**. For example, measurable percent improvements in memory tests, or restoring memory function that was lost, would demonstrate it “exceeds previous solutions.”
- *Multi-actor development:* Multiple teams (academic, government, industry) **building similar systems** is a sign of maturity – e.g. more than one company with working prototypes, or devices approaching regulatory approval. Patents on concrete designs, vendor datasheets for memory-prosthesis-capable implants, or roadmaps from authoritative bodies would support this.

6. **Evidence (10–20 recent, reliable sources)**

7. **Hippocampal prosthesis improves memory in human patients – Couture et al., *Frontiers in Comp. Neuroscience* (Feb 2024):** A Wake Forest/USC research team implanted multielectrode arrays in 14 epilepsy patients and delivered content-specific stimulation patterns in the hippocampus during memory tasks. They found this “memory prosthetic” stimulation significantly boosted recognition of images – in subjects with memory impairment receiving bilateral hippocampal stimulation,

performance improved roughly 4-fold more often than it worsened[3][4]. This provides the first peer-reviewed demonstration that tailored electrical codes can enhance human memory encoding, validating the feasibility of a memory prosthesis.

8. **News: First successful neural prosthetic to recall specific memories – Atrium Health Wake Forest (Feb 2024):** Reports on the above study as “the first successful use of a neural prosthetic device to recall specific memories” in humans[5]. Using a patient’s own neural firing patterns, the implant delivered spatio-temporal stimulation in the hippocampus, yielding detectable memory improvements in ~22% of trials overall. Notably, almost 40% of memory-impaired patients with bilateral implants showed significant gains in memory performance[6]. This press release underscores that memory recall was enhanced without adverse effects, marking a breakthrough in memory restoration technology.
9. **Human trial shows 11–54% memory improvement with hippocampal implant – USC Viterbi News (Oct 2024):** In a collaborative clinical trial with 24 epileptic volunteers, researchers tested a prototype hippocampal memory prosthesis. The device used each person’s intracranial electrodes and a computational model to detect and reinforce memory encoding. Results showed volunteers with the prosthesis had 11% to 54% better memory test scores compared to control conditions[7]. This significant boost – observed in real patients recalling images over seconds to days – constitutes a proof-of-concept in humans[8]. The article notes that this was achieved by “piggybacking” on existing epilepsy implants and an external processor, and it paved the way for upcoming fully implantable versions[9].
10. **Closed-loop stimulation targeting memory networks – Ezzyat et al., Cerebral Cortex (Jan 2024):** A multi-center clinical study (47 patients) demonstrated that closed-loop brain stimulation can reliably improve episodic memory when delivered to optimal sites. A machine-learning model monitored brain signals during a word recall task and triggered stimulation in the lateral temporal cortex during predicted “poor encoding” moments. Memory retrieval improved significantly – but only when electrodes were near key white-matter pathways and strongly connected to the brain’s memory network[10][11]. Stimulation at those ideal locations yielded the largest memory gains and reduced low-frequency brain activity associated with memory failure. These findings not only confirm that adaptive stimulation enhances memory, but also show how to optimize electrode targeting for effective memory prosthetics.
11. **60-channel wireless memory prosthesis prototype (in vivo validation) – Rizzuto et al., Brain Stimulation 2025 (press release, Jan 2026):** Nia Therapeutics (USA) announced a fully implantable Smart Neurostimulation System (SNS) that was tested in large animals as a closed-loop memory prosthesis[12]. The wireless implant can record from 60 electrodes across four brain regions – 10× more channels than current clinical devices – reflecting the distributed nature of memory circuits[13]. In chronic sheep studies, the SNS system showed stable long-term performance: it could decode brain states with high accuracy and deliver programmed stimulation that reliably modulated neural activity (e.g. dose-dependent shifts in hippocampal EEG rhythms)[14]. Histology showed no tissue damage. This device builds on human research where adaptive stimulation during poor-encoding periods improved recall ~20%[15], and Nia is now preparing for first-in-human trials in TBI patients by 2026[16]. (Source: Nia Therapeutics press release via Business Wire.)\*

12. **Emerging multi-channel implants (industry & academia) – Fisher et al., review in *Brain* (2024):** A recent review of deep brain neurostimulation technologies notes that millimeter-scale, multi-channel brain implants are nearing clinical translation for memory and other cognitive applications. For example, Nia Therapeutics and CorTec Neuro (Germany) have each run pre-clinical trials on skull-mounted implantable stimulators, while others like Motif Neuro are testing novel dural stimulators[17]. These systems, larger than earlier micro-devices, can house more processing and electrodes on-device. The review highlights that such multi-target closed-loop devices – including Neuralink’s high-channel BCI now in clinical trial – are part of a wave of neurotech aimed at network-level disorders (like memory loss) rather than single focal lesions.
13. **EU consortium advancing memory prosthesis in primates – MEMOPROSTHETICS project report (EU ERC, July 2025):** An EU-funded research program (CNRS, France) is developing a neuroprosthesis for memory circuits in non-human primates[18][19]. They implanted dozens of electrodes in three brain areas (hippocampus, entorhinal cortex, prefrontal cortex) to record and stimulate neural networks involved in memory encoding[20]. So far, the team has identified neural oscillation changes correlated with memory tasks and begun testing whether targeted electrical stimulation can improve memory formation[21][22]. Early results showed that certain high-amplitude stimulations in hippocampus or entorhinal cortex can disrupt memory, guiding the search for safe, pro-memory stimulation parameters[23]. The project is now optimizing stimulation protocols and working to miniaturize the system into a fully implantable device, aiming to pave the way for clinical trials in Alzheimer’s or brain-injury patients[24].
14. **Review: Engineering a hippocampal memory prosthesis – Liu et al., *Curr. Opinion Biomed. Eng.* (Dec 2022):** This review summarizes two decades of progress toward hippocampal prosthetic memory devices, highlighting both neuroscience and hardware advances. It notes that modern neural “interrogation” tools (multi-electrode arrays, optogenetics, etc.) have mapped hippocampal memory codes, and early-stage prosthetics have been tested in animals[25][26]. For example, recent experiments connected live rodent hippocampus slices with a neuromorphic memristor circuit that acted as an artificial synapse – showing that a silicon device could influence hippocampal neurons in vitro[27]. The authors emphasize bio-inspired approaches (neuromorphic hardware mimicking neuronal firing) as a path to restore memory function in Alzheimer’s disease, and cite that hippocampal prosthetic models have already shown success in rodents, monkeys, and human feasibility studies.
15. **Adaptive 40 Hz stimulation chip boosts memory in Alzheimer’s mice – Lv et al., *Nature Commun.* 16:5948 (July 2025):** Chinese researchers developed “NeuroRevive-FlexChip,” a flexible neural implant that combines dopamine sensing with electrical stimulation in the hippocampus[28]. In Alzheimer’s-model mice, this chip applied 40 Hz stimulation to CA1 while monitoring dopamine in real time. The treatment restored more normal dopamine release and reduced pathological hyper-synchrony in hippocampal activity[29]. Treated mice showed modest improvements in spatial memory (Y-maze test) and even a reduction in  $\beta$ -amyloid deposition, compared to controls[30][31]. This innovative closed-loop neuromodulator – which targets a neurochemical aspect (dopamine) alongside electrical activity – underscores the expanding toolkit for memory prosthesis research, though it remains at preclinical stage.
16. **Maturity score (1–7) and reasoning**  
**Score: 4 (Proof-of-Concept demonstrated).**

**Rationale:** The concept of a memory prosthesis has progressed well beyond theory (Levels 1–2) into tangible laboratory and *in vivo* demonstrations. **Multiple teams have built and tested prototype systems that restore memory functions in animals and even human patients**, satisfying the criteria for at least Level 3. In fact, the evidence shows we have reached **Level 4: Proof-of-Concept**. Recent human trials and advanced prototypes indicate that the technology is functional and addressing real-world requirements, though not yet a market product:

- *Level 3 vs 4:* We have **laboratory prototypes proven in humans**, not just isolated lab benchtop tests. For example, the 2024 Frontiers study demonstrated a **working hippocampal prosthesis in human patients, measurably improving their memory performance**[\[3\]](#)[\[4\]](#). This solved a key previously blocking problem – that is, encoding and re-injecting meaningful memory “codes” to boost recall – something only theorized before. Likewise, in monkeys and rodents, closed-loop implants have shown they can influence memory-related signals. These successes rule out Level 2 (“just basic lab verification”) and firmly achieve Level 3. Moreover, the devices have moved from racks of equipment to **miniaturized implantable prototypes**: e.g. Nia’s 60-channel wireless implant and the ERC group’s multi-electrode primate implant, which indicates engineering viability beyond a one-off demo[\[12\]](#)[\[20\]](#). The presence of a **dedicated startup (Nia Therapeutics) building medical-grade hardware** and preparing for clinical trials is a strong indicator we are at PoC stage and pushing toward productization[\[16\]](#).
- *Evidence of Level 4 (PoC):* The emerging prototypes meet many **commercialization requirements in functionality**. Nia’s fully implantable device, for instance, is wireless, closed-loop, and high-channel-count – features necessary for a practical therapy (existing clinical neurostimulators were insufficient at 4–6 channels)[\[13\]](#). It has been validated in chronic animal tests with stable performance and safety[\[14\]](#), suggesting robustness. Similarly, academic teams are already focusing on **miniaturizing and integrating components (sensors, stimulators, on-chip models)** into implantable packages[\[9\]](#). The USC group’s plan for a “fully implantable, polymer-based device” within 1–2 years shows a clear path to a deployable prototype[\[9\]](#). These are all hallmarks of a PoC transitioning out of the lab. Importantly, the approach **clearly exceeds previous solutions** – there is currently no alternative treatment that can restore memory loss from conditions like dementia or brain injury. Early human tests achieved up to ~50% improvement on memory tasks that would otherwise be unassisted[\[32\]](#), a benefit far beyond any classical cognitive training or drugs can provide. This validates the value proposition needed for commercialization.
- *Why not Level 5 or above?* The technology is not yet at a stage of widespread competition or commercial deployment. **No memory prosthesis is on the market**, and while one startup (and perhaps one or two consortium efforts) are in the race, we do not yet see “several well-capitalized market actors” with products (Level 5). We have one notable venture-backed company entering first human trials, but no evidence of multiple companies selling devices or strong customer demand – those would correspond to Levels 6–7. In short, the concept has moved from academia into early clinical translation (PoC/prototype phase), but *not* into full product development cycles or scaling manufacturing. Key gaps remain before the next maturity level: for instance, **regulatory approval and large-scale trials are outstanding**, and long-term reliability/cost issues have not been fully ironed out (the implants have only been tested chronically in a handful of animals or short human trial sessions). We also haven’t seen competition between firms or significant private-sector investment beyond initial startups. Achieving Level 5+ will require demonstrating efficacy in broader patient populations (e.g. successful Phase I/II trials of a memory prosthesis for Alzheimer’s or TBI), securing regulatory approvals, and attracting major industry players or partnerships to finance product launch.

None of these has happened yet – thus the **maturity remains at the proven prototype stage (Score 4)**, with a clear path forward but still substantial development to go.

*Sub-component breakdown:* This ART involves a convergence of sub-technologies – neural interface hardware, decoding algorithms, and closed-loop stimulation therapy – each at slightly different maturity, but overall comparable. The **implant hardware** (high-channel neural stimulators) is quite advanced (arguably entering Level 4 on its own, as devices like the 60-channel SNS exist and are nearing clinical testing)[12]. The **memory decoding algorithms and stimulation paradigms** have been validated in research settings (Level 3–4, given human and primate studies showing they work but with room to improve consistency[33][34]). These components function together, and the overall system’s maturity is essentially the sum of its parts. Since all sub-components aim at the same application (restoring episodic memory) and must be integrated, we treat the bundle as a single technology. **Each piece has cleared the “it works in principle” hurdle, and the combined system has been demonstrated in a clinically relevant scenario – thus the integrated maturity is Level 4.** Continued progress (to Level 5) will likely occur as these prototypes enter formal clinical trials and as more companies/institutions invest in competing implementations, which, according to the evidence, is the anticipated next step within the coming decade.

## Group 5 – Robotics & Physical Autonomy

### ART 05.029 Self-Driving Vehicles

#### ART extraction

- **Primary capability (claimed)**
- Road vehicles that can drive for extended periods on public roads **without continuous human control**, potentially reaching unsupervised “driverless” operation in some operational design domains (ODDs).
- Software-defined driving (perception → prediction → planning/control, or end-to-end learned stacks) that can be validated, monitored, updated, and scaled across fleets.
- Safety-structured autonomy: redundancy, health monitoring, and safe fallback behavior as systems move from supervised to unsupervised operation.
- **Key sub-components / variants**
- Sensor suites and fusion: camera-centric vs. multimodal (camera + radar + lidar/ranging), and redundancy strategies.
- High-precision localization and mapping: HD-map–dependent geofencing vs. reduced-map / perception-first generalization.
- Onboard compute and software stack: modular pipelines vs. end-to-end learned driving; OTA updates and continuous improvement via fleet data.
- Safety engineering and assurance: scenario-based validation, safety case frameworks, SOTIF-oriented hazard reasoning, in-service monitoring.
- Governance & oversight: crash/incident reporting regimes, type approval / deployment permits, liability frameworks.

- Remote operations: remote assistance for rare exceptions vs. direct teleoperation; human factors, latency, and operational boundaries.
- Robustness constraints: extreme weather/visibility degradation; construction/temporary control; cybersecurity.
- **Maturity indicators that “count” as evidence**
- **Commercial deployment with driverless operation** (even if geofenced/limited ODD) and paying customers.
- Publicly documented **regulatory approvals** (deployment permits; authorization to charge fares; type approval / legal frameworks).
- **Measured in-service safety outcomes** (e.g., claims/crash-rate benchmarks, injury/airbag deployment outcomes) with transparent methodology.
- **Operational-scale data** (tens of millions of miles; sustained reporting pipelines; collision reporting volumes).
- **Standards and assurance toolchains** (SOTIF, scenario-based evaluation, safety-case standards, assumptions standards, OTA engineering standards) that enable certification and scaling.

**Evidence (10–20 recent, reliable sources)**

#### **Standards and engineering frameworks for safety, testing, and OTA updates**

1) **Title:** ISO 21448:2022 — *Road vehicles — Safety of the intended functionality (SOTIF)*

**Organization:** ISO[1]

**Venue/type:** International standard (safety assurance guidance for functional insufficiencies)

**Publication date:** June 2022

**Link (URL):** <https://www.iso.org/standard/77490.html>

**What it reports / why it matters:** Defines a structured framework for addressing hazards that arise from functional insufficiencies (especially relevant to perception/decision systems), which is foundational for plausibility and for regulator-ready assurance cases beyond classic functional safety. [2]

2) **Title:** ISO 34502:2022 — *Road vehicles — Test scenarios for automated driving systems — Scenario based safety evaluation framework*

**Organization:** ISO

**Venue/type:** International standard (scenario-based ADS safety evaluation)

**Publication date:** November 2022

**Link (URL):** <https://www.iso.org/standard/78951.html>

**What it reports / why it matters:** Provides a scenario-based safety evaluation process for ADS (notably for limited access highways), directly supporting scalable validation approaches needed to move from pilots to larger deployments. [3]

3) **Title:** ANSI/UL 4600 (Edition 2) — *Evaluation of Autonomous Products*

**Organizations:** ANSI[4]; UL[5]

**Venue/type:** Safety standard (safety case / evaluation standard for autonomous products)

**Publication date:** March 2022 (Published Date)

**Link (URL):**

[https://www.shopulstandards.com/ProductDetail.aspx?productId=UL4600\\_2\\_S\\_2](https://www.shopulstandards.com/ProductDetail.aspx?productId=UL4600_2_S_2)

0220315

**What it reports / why it matters:** The existence of an updated, formal safety-evaluation standard indicates the field is beyond pure R&D and is aligning around deployability artifacts (safety cases, hazard coverage, assessment expectations). [6]

4) **Title:** IEEE 2846-2022 — *IEEE Standard for Assumptions in Safety-Related Models for Automated Driving Systems*

**Organization:** IEEE[7]

**Venue/type:** Standard (assumptions/foreseeable scenarios for safety-related ADS models)

**Publication date:** April 2022

**Link (URL):** <https://standards.ieee.org/ieee/2846/10831/>

**What it reports / why it matters:** Codifies a minimum set of assumptions and reasonably foreseeable scenarios that must be considered in safety-related ADS models—an important step toward verifiable, auditable safety arguments at scale. [8]

5) **Title:** ISO 24089:2023 — *Road vehicles — Software update engineering*

**Organization:** ISO

**Venue/type:** International standard (process requirements/recommendations for vehicle software updates)

**Publication date:** February 2023

**Link (URL):** <https://www.iso.org/standard/77796.html>

**What it reports / why it matters:** Establishes software update engineering requirements spanning organizations and systems, supporting the OTA-driven development path described in the ART and linking maturity to controlled, traceable field updates. [9]

#### **Government and regulatory evidence for market-readiness and oversight**

6) **Title:** *Connected & Automated Mobility 2025: Realising the benefits of self-driving vehicles in the UK*

**Organization:** UK Department for Transport[10] (presented to Parliament)

**Venue/type:** Government report/roadmap

**Publication date:** August 2022

**Link (URL):**

<https://assets.publishing.service.gov.uk/media/62ff438c8fa8f504cdec92df/cam-2025-realising-benefits-self-driving-vehicles.pdf>

**What it reports / why it matters:** Summarizes UK policy, timelines, and international regulatory alignment, including references to ALKS regulatory evolution and cybersecurity/software-update regulatory focus—evidence of institutionalization beyond lab prototypes. [11]

7) **Title:** *Automated Vehicles Act 2024 — Explanatory Notes*

**Organization:** United Kingdom[12] (Explanatory Notes prepared by Department for Transport)

**Venue/type:** Government legal framework documentation

**Publication date:** May 2024 (Royal Assent referenced as 20 May 2024)

**Link (URL):**

[https://www.legislation.gov.uk/ukpga/2024/10/pdfs/ukpgaen\\_20240010\\_en.pdf](https://www.legislation.gov.uk/ukpga/2024/10/pdfs/ukpgaen_20240010_en.pdf)

**What it reports / why it matters:** Documents a modern legal framework for regulating automated vehicles, supporting maturity via clarified authorization concepts, operational regulation, and incident/marketing restriction mechanisms. [13]

8) **Title:** CPUC approves permits for Cruise and Waymo to charge fares for driverless passenger service in San Francisco

**Organization:** California Public Utilities Commission[14]

**Venue/type:** Government regulatory approval (commercial driverless passenger service authorization)

**Publication date:** August 2023

**Link (URL):** <https://www.cpuc.ca.gov/news-and-updates/all-news/cpuc-approves-permits-for-cruise-and-waymo-to-charge-fares-for-passenger-service-in-sf-2023>

**What it reports / why it matters:** Confirms commercial driverless ride service authorization (charge fares, any time of day) for Cruise[15] and Waymo[16] in San Francisco[17]—strong maturity evidence that the technology is operationally deployed under regulator conditions (though still ODD-bounded). [18]

9) **Title:** California DMV approves Mercedes-Benz automated driving system for certain highways and conditions

**Organization:** California Department of Motor Vehicles[19]

**Venue/type:** Government deployment permit / regulatory approval

**Publication date:** June 2023

**Link (URL):** <https://www.dmv.ca.gov/portal/news-and-media/california-dmv-approves-mercedes-benz-automated-driving-system-for-certain-highways-and-conditions/>

**What it reports / why it matters:** Grants a deployment permit allowing Mercedes-Benz[20] to commercially offer a Level 3 system on designated highways with explicit ODD limits (e.g., daylight, ≤40 mph, excludes heavy rain/fog/construction zones), demonstrating regulated commercialization and the persistence of environmental constraints. [21]

10) **Title:** California DMV — Autonomous Vehicle Collision Reports (public reporting portal)

**Organization:** California DMV

**Venue/type:** Government dataset/registry (mandatory collision reporting)

**Publication date:** February 2026 (page states “As of February 20, 2026”)

**Link (URL):** <https://www.dmv.ca.gov/portal/vehicle-industry-services/autonomous-vehicles/autonomous-vehicle-collision-reports/>

**What it reports / why it matters:** Indicates collision reporting obligations and the scale of reported real-world operations (“939 Autonomous Vehicle Collision Reports” as of Feb 20, 2026), supporting maturity analysis via sustained, institutionalized incident reporting pipelines. [22]

11) **Title:** Third Amended Standing General Order 2021-01 — Incident reporting for ADS and Level 2 ADAS

**Organization:** National Highway Traffic Safety Administration (NHTSA)[23]

**Venue/type:** Government order / reporting requirement

**Publication date:** April 2025 (dated April 24, 2025; effective June 16, 2025)

**Link (URL):** [https://www.nhtsa.gov/sites/nhtsa.gov/files/2025-04/third-amended-SGO-2021-01\\_2025.pdf](https://www.nhtsa.gov/sites/nhtsa.gov/files/2025-04/third-amended-SGO-2021-01_2025.pdf)

**What it reports / why it matters:** Formalizes and updates mandatory incident/crash reporting requirements for ADS and Level 2 systems, which is a key maturity signal: regulators are actively managing operational risk with data-driven oversight rather than treating AVs as purely experimental. [24]

12) **Title:** Report to Congress (Biannual) — NHTSA research and rulemaking activities on vehicles equipped with ADS

**Organization:** NHTSA (USDOT)

**Venue/type:** Government report (rulemaking + research status update)

**Publication date:** July 2025

**Link (URL):** <https://www.nhtsa.gov/sites/nhtsa.gov/files/2025-07/report-congress-research-rulemaking-automated-driving-systems-july-2025-tag.pdf>

**What it reports / why it matters:** Shows active federal efforts to adapt oversight (e.g., reporting amendments, exemption program changes, rulemaking initiatives) and to develop assessment methodologies—evidence that commercialization is “real enough” to merit continuous regulatory infrastructure. [25]

13) **Title:** Understanding Safety Challenges of Vehicles Equipped with ADS — Analysis of ADS Disengagements

**Organization:** U.S. Department of Transportation (USDOT)[26] (HASS COE)

**Authors:** Mubassira Khan[27] et al.

**Venue/type:** Government technical report

**Publication date:** August 2024

**Link (URL):** [https://www.transportation.gov/sites/dot.gov/files/2024-08/HASS\\_COE\\_Understanding\\_Safety\\_Challenges\\_of\\_Vehicles\\_Equipped\\_with\\_ADS\\_Aug2024.pdf](https://www.transportation.gov/sites/dot.gov/files/2024-08/HASS_COE_Understanding_Safety_Challenges_of_Vehicles_Equipped_with_ADS_Aug2024.pdf)

**What it reports / why it matters:** Analyzes California disengagement reports (2022–2023) and notes reporting inconsistency (e.g., distinct descriptions in only ~4% of reports) and that human drivers initiated disengagements in a large share of cases—evidence that scaling validation and consistent reporting remain maturity bottlenecks. [28]

#### Fielded-system safety outcomes and scaling evidence

14) **Title:** Comparative safety performance of autonomous- and human drivers: a real-world case study of the Waymo Driver

**Authors/organizations:** Luigi Di Lillo[29] et al.; Swiss Re[30] + Waymo (industry/academia affiliations listed)

**Venue/type:** Peer-reviewed paper (Heliyon)

**Publication date:** July 2024

**Link (URL):** <https://pubmed.ncbi.nlm.nih.gov/39114012/>

**What it reports / why it matters:** Proposes and demonstrates a claims-based comparative safety method using large insurance baselines (e.g., hundreds of thousands of claims and large driving exposure) and reports that the Waymo Driver improves safety vs. calibrated human baselines—direct plausibility/maturity evidence from real deployments rather than simulations alone. [31]

15) **Title:** Comparison of Waymo Rider-Only crash rates by crash type to human benchmarks at 56.7 million miles

**Authors/organization:** Kristofer D Kusano[32] et al.

**Venue/type:** Peer-reviewed paper (Traffic Injury Prevention)

**Publication date:** Epub May 2025 (journal issue Oct 2025)

**Link (URL):** <https://pubmed.ncbi.nlm.nih.gov/40378124/>

**What it reports / why it matters:** Uses 56.7 million rider-only miles (through end of Jan 2025) and finds statistically significant crash-rate reductions vs matched human benchmarks

across outcomes (e.g., notable reductions for vehicle-to-vehicle intersection crashes), indicating an at-scale driverless service with measurable safety performance. [33]

### **Operational safety cases, regulation-compliance practice, and edge-condition limits**

16) **Title:** Assuring Regulatory Compliance of Connected and Automated Vehicles during their Operational Lifetime

**Organization:** CITA[34] / IAMTS (whitepaper series)

**Venue/type:** Technical whitepaper / best-practice report (industry standards/testing ecosystem)

**Publication date:** April 2023 (issued 2023-04-21)

**Link (URL):** [https://citainsp.org/wp-content/uploads/2023/04/IAMTS0004202304\\_V1.1.pdf](https://citainsp.org/wp-content/uploads/2023/04/IAMTS0004202304_V1.1.pdf)

**What it reports / why it matters:** Discusses how UNECE regulation scope (including ALKS changes) and cybersecurity/software-update management requirements (R155/R156) affect lifecycle compliance, and emphasizes multi-pillar validation (test track, real world, simulation, in-service monitoring)—evidence of maturation toward lifecycle governance. [35]

17) **Title:** UL 4600: What to Include in an Autonomous Vehicle Safety Case

**Author:** Philip Koopman[36]

**Venue/type:** Peer-reviewed technical article (IEEE Computer)

**Publication date:** May 2023

**Link (URL):**

[https://users.ece.cmu.edu/~koopman/pubs/Koopman2023\\_UL4600\\_Safety\\_Case.pdf](https://users.ece.cmu.edu/~koopman/pubs/Koopman2023_UL4600_Safety_Case.pdf)

**What it reports / why it matters:** Explains why road testing alone cannot scale to the assurance levels needed for driverless deployment and frames UL 4600 as a “safety case” umbrella—supporting the ART’s claim that formalized redundancy, hazard coverage, and lifecycle safety monitoring are essential to maturity. [37]

18) **Title:** Performance Verification of Autonomous Driving LiDAR Sensors under Rainfall Conditions in Darkroom

**Authors/organization:** Jaeryun Choe[38] et al. (Korea Conformity Laboratories affiliation shown)

**Venue/type:** Peer-reviewed experimental paper (Sensors)

**Publication date:** December 2023 (Published 19 Dec 2023)

**Link (URL):** <https://www.mdpi.com/1424-8220/24/1/14>

**What it reports / why it matters:** Quantifies LiDAR behavior under controlled rainfall conditions (e.g., 0–40 mm/h; 10–30 m) and supports the ART’s constraint claim that adverse weather/visibility remains a technical limiter—important for plausibility boundaries and ODD definition. [39]

19) **Title:** A Roadmap Towards Remote Assistance: Outcomes from Multidisciplinary Workshop at the 2023 Intelligent Vehicles Symposium

**Repository/organization:** German Aerospace Center (DLR)[40] eLib record

**Authors:** Maytheewat Aramrattana[41] et al.

**Venue/type:** Peer-reviewed conference paper (Springer CCIS / HCI International 2024)

**Publication date:** June 2024 (DLR eLib “Date: 8 June 2024”)

**Link (URL):** <https://elib.dlr.de/204846/>

**What it reports / why it matters:** Identifies remote assistance as an event-driven support layer (high-level guidance rather than continuous driving) and outlines research gaps in human factors, remote station design, and HAV design—evidence that remote assistance remains part of practical deployments, consistent with the ART description. [42]

20) **Title:** Improving road user perception in adverse weather: An augmented HMI for remote assistants of automated vehicles

**Author:** Andreas Schrank[43] et al.

**Venue/type:** Peer-reviewed experimental paper (Transportation Research Part F; open access)

**Publication date:** August 2025

**Link (URL):**

<https://www.sciencedirect.com/science/article/pii/S1369847825001810>

**What it reports / why it matters:** Demonstrates via controlled experiment (34 participants; fog varied) that augmenting remote-assistance interfaces with sensor-derived information can reduce collisions and improve situation awareness—directly relevant to the ART’s claim that remote assistance may remain necessary for rare edge cases, especially in poor visibility. [44]

21) **Title:** AI Safety Assurance for Automated Vehicles: A Survey on Research, Standardization, Regulation

**Author:** Lars Ullrich[45] et al.

**Venue/type:** Preprint (arXiv) with journal-reference metadata

**Publication date:** April 2025 (arXiv submission date)

**Link (URL):** <https://arxiv.org/abs/2504.18328>

**What it reports / why it matters:** Synthesizes the state of AI safety assurance for automated vehicles across technical research and standards/regulation, highlighting that safety assurance for increasingly learned stacks remains an active, unresolved maturity barrier even as deployments expand. [46]

**Maturity score (1–7) and reasoning**

**Final maturity score: 6 [47]**

**Why level 6 fits, with explicit rubric mapping**

**What evidence rules out levels 1–4 (theory, lab confirmation, lab prototype, PoC only):**

Commercial and regulated deployments exist and are being evaluated with real-world safety and incident data. California’s regulator explicitly approved driverless passenger service with fare-charging authorizations in San Francisco (i.e., not merely a test) [18], and California’s DMV granted a deployment permit enabling consumer-facing Level 3 operation (within defined highway/condition constraints) [21]. Moreover, peer-reviewed studies evaluate deployed driverless operations using claims/crash-rate methodologies at tens of millions of miles scale, which goes well beyond PoC demonstrations. [48]

**What evidence rules out level 5 (post-PoC, still primarily “finishing production prototype”):**

Level 5 would be consistent with multiple actors racing toward production prototypes, but level 6 requires actual delivery to customers. The CPUC authorization is specifically about commercial passenger service with driverless vehicles (service delivery), [18] and the crash-

rate study explicitly analyzes 56.7 million rider-only miles through January 2025, implying sustained, real-world driverless operations rather than a limited pilot. [33]

### **Why the evidence supports level 6 (products delivered; scaling; expanding governance):**

- **Products/services delivered:** Driverless passenger service authorized to charge fares in a major city; regulated Level 3 system permitted for consumer use in defined highway conditions. [49]
- **Growing operational footprint & institutional oversight:** California's collision reporting system shows an extensive body of reported incidents over time (939 collision reports received as of Feb 20, 2026), indicating ongoing operations under a reporting regime rather than isolated demos. [22]
- **Measured performance at scale:** Peer-reviewed work compares deployed driverless operations against human benchmarks using insurance claims and crash-rate typologies across tens of millions of driverless miles. [48]
- **Regulatory scaffolding for scaling:** Federal crash/incident reporting requirements (Third Amended SGO) and NHTSA's ongoing research/rulemaking reports show that scaling is coupled to evolving, formal oversight pathways. [50]

### **What is still missing to justify level 7**

Level 7 requires that **competing products are being delivered and customer demand is rising**, with broad competition and growth financing across a wide clientele. The evidence above supports real deployments, but also shows that: - Operations and commercialization remain **ODD-limited** (explicit restrictions in the Level 3 deployment permit; and continuing attention to scenario-based validation, reporting, and safety case development). [51]

- **Edge-case handling and adverse weather** are still active constraints (LiDAR degradation under rainfall; remote assistance and human factors research for poor visibility), indicating incomplete robustness for broad, unconstrained scaling. [52]
- Reporting/validation infrastructure is still being refined (e.g., disengagement narrative sparsity and inconsistent reporting noted by USDOT's HASS COE), which is typical of systems not yet in ubiquitous, commodity-scale deployment. [28]

Together, these suggest the ecosystem is not yet at the "widely delivered competing products with clearly rising demand" threshold implied by level 7, especially for *routine autonomy across wide regions and conditions*.

### **Sub-component maturity breakdown and aggregation**

- **Geofenced Level 4 robotaxi services (driverless, curated ODDs):** ~6
- Supported by commercial authorization and large-scale safety analysis at tens of millions of driverless miles. [53]
- **Highway Level 3 consumer availability (narrow ODD, strict conditions):** ~6
- Supported by deployment permitting that explicitly allows public offering under defined conditions (not just testing). [21]
- **Safety assurance / validation toolchain maturity (standards + reporting regimes):** ~6
- Strong standardization (SOTIF, scenario-based evaluation, safety case standards, modeling assumptions) and mandatory incident reporting; still evolving, but clearly institutionalized. [54]

- **Robustness in extreme weather & remote exception handling:** ~4–5
- Active research shows performance limits in poor visibility and ongoing dependencies on remote assistance design and procedures, suggesting incomplete robustness for broad ODD autonomy. [52]
- **OTA-driven scaling processes (engineering formalization):** ~6
- ISO 24089:2023 indicates mature process standardization for software updates, a prerequisite for safe fleet-scale iteration. [9]

**Aggregation approach:** This ART is a bundle where the core “driverless road vehicle” functionality is shared across variants but deployed unevenly by ODD and vehicle class. The score uses a **practical weighted view**: commercially delivered driverless services and regulated Level 3 offerings justify level 6, while weather/edge-case robustness and broad-area generalization remain below the level-7 threshold. [55]

## ART 05.030 Drone Swarms & Aerial Robots

### 1. ART extraction

**A. Primary capability:** Enabling autonomous *drone swarms* – fleets of UAVs that coordinate in real time to cover large, complex 3D environments without fixed infrastructure. Such swarms can be rapidly deployed and self-navigate with minimal human control, achieving tasks more flexibly and robustly than any single large drone.

### B. Key sub-components/variants:

- **Multi-UAV coordination algorithms:** Methods for real-time sharing of maps, sensor data, and tasks among drones, with dynamic task allocation and collision avoidance (each drone adjusting its path based on others).
- **Autonomous navigation & perception:** Onboard vision/range sensors and localization enabling each drone to avoid obstacles and operate without GPS or external markers (vital for cluttered or GPS-denied spaces).
- **Heterogeneous drone fleets:** Integration of different-sized aerial robots or even mixed air/ground/underwater vehicles working together, including high-altitude “mothership” drones guiding lower units and varied sensor payloads on different drones.
- **Communication networks:** Reliable, secure links (mesh networks, 5G, etc.) for inter-drone communication and swarm command, including infrastructure for beyond-visual-line-of-sight (BVLOS) control and data sharing.
- **Human-swarm interfaces & fail-safes:** High-level supervisory control systems for one operator to oversee many drones (defining objectives and boundaries), with autonomous fail-safes to handle communication loss, drone failures, and comply with airspace safety rules.
- **Power and endurance management:** Strategies to mitigate limited battery life (e.g. automated recharging/docking, optimal task sequencing, use of long-endurance nodes) so that swarms can persist on long missions despite individual drones’ short flight times.
- **Regulatory compliance frameworks:** Operational protocols and emerging regulatory provisions that allow swarm deployments (e.g. waivers for one-to-many drone control) while ensuring public safety and privacy in civilian airspace.

**C. Maturity indicators:** Key evidence of progress would include **field trials and pilot deployments** of multi-drone swarms performing useful tasks (e.g. disaster response, surveillance, mapping) under real-world conditions. **Proof-of-concept demonstrations** showing multiple drones autonomously coordinating (with minimal human input) to achieve objectives – especially in GPS-denied or hazardous environments – would signal high plausibility. **Prototype systems and products** reaching end-users (e.g. military exercises, industrial inspections) and **regulatory milestones** (such as waivers or new rules enabling

swarm operation) indicate rising maturity. Also, the emergence of **multiple well-funded companies or programs** competing in this space, and **metrics** like number of drones in a coordinated mission, autonomy in complex environments, or one-operator-to-many-drone control ratio, would demonstrate both technical feasibility and steps toward scalable deployment.

## 2. Evidence (10–20 recent, reliable sources)

- **Zhou et al., Zhejiang Univ. – Science Robotics (May 2022): “Swarm of micro flying robots in the wild.” (Peer-reviewed)** Demonstrated a swarm of palm-sized drones autonomously navigating a dense bamboo forest with on-board sensing and no external infrastructure. A new trajectory planner enabled inter-drone collision avoidance and obstacle evasion in real time, achieving complex 3D flight as a coordinated group – a task previously infeasible for swarms in such cluttered environments[1][2]. This real-world field trial confirms the plausibility of self-directed drone swarms operating in GPS-denied, hazardous terrain.
- **Gui et al., Def. Innov. Inst. (China) – MDPI Drones 7(6):337 (May 2023): “Decentralized Multi-UAV Cooperative Exploration Using Dynamic Centroid-Based Area Partition.” (Peer-reviewed)** Proposes an algorithm for a team of UAVs to efficiently explore unknown areas by dynamically partitioning the 3D space among drones. Each drone autonomously maps its region and shares minimal data (poses/weights) over a 5G Wi-Fi network. In simulations and a **3-UAV indoor experiment**, the method reduced redundant coverage and improved collective mapping speed[3][4]. The successful practical trial of three drones collaborating in real time to map an area demonstrates a solved sub-problem (coordinated exploration) and serves as a proof-of-concept for swarm autonomy in search-and-rescue scenarios.
- **U.S. GAO – Science & Tech Spotlight: Drone Swarm Technologies (Sep 2023): (Government report)** A high-level assessment of drone swarms’ status, noting that algorithms and AI have recently improved swarm decision-making, and swarms of “at least three and up to thousands” of drones coordinating with limited human control are now technically feasible[5][6]. However, GAO emphasizes that current real-world use of swarms is still very limited – mostly constrained to simple, pre-planned tasks like entertainment light shows – and more dynamic missions (e.g. real-time target tracking with many drones) remain challenging. The report also flags that **regulations lag behind**: as of now, U.S. federal rules don’t allow one operator to control multiple drones without a waiver[7]. This highlights that while the science is proven and prototypes exist, routine deployment is held back by safety, security, and regulatory hurdles rather than fundamental technology gaps.
- **NASA ESTO & Clemson Univ. – FireSense Project Overview (2022): “AI-Enabled Drone Swarms for Fire Detection, Mapping, and Modeling.” (Agency program announcement)** Describes a newly funded NASA project to develop heterogeneous drone swarms for wildfire monitoring[8]. The planned system uses a **hierarchical fleet** – high-altitude UAVs as command relays and many lower UAVs with thermal and visual sensors – to continuously map fires and predict spread. It focuses on on-board AI for real-time collaborative perception (to overcome bandwidth limits) and will create a **digital twin** environment for testing swarm strategies[8][9]. The project’s goals (e.g. multi-UAV autonomous coverage of a wildfire over long durations with minimal human input) indicate that major research agencies find the concept plausible and are actively working to mature it. This is evidence of accelerating progress towards field-ready swarm systems, with emphasis on software updates, simulation training, and integration into existing communication infrastructure.
- **VTT (Finland) – FireMan Project News (Aug 2022): “Using drone swarms to monitor and combat future wildfires.” (Research consortium update)** Reports on a Finnish R&D project

developing a **semi-autonomous swarm** for wildfire surveillance. Early simulations show drones can collectively encircle a fire and adapt their formation based on wind and fire spread – for example, sharing positions and automatically spacing themselves into an elongated ellipse downwind to avoid hazardous smoke[10]. Initial test flights in 2022 validated basic capabilities, and a full multi-drone demo in a controlled burn is planned for 2024[11][12]. Researchers aim to allow **one firefighter to supervise multiple drones**: “one pilot to operate several drones with the support of swarm intelligence,” rather than today’s one-drone-per-pilot paradigm[13]. This international effort underscores both the promise (faster, safer situational awareness for wildfire response) and the remaining work in human-swarm interfaces and trust. It also suggests that within a few years, such systems could transition from prototype to real deployments in public safety.

- **Wu, Rastgaar, Mahmoudian – IFAC-PapersOnLine Vol.58(20) (2024): “Heterogeneous Multi-Robot (UAV-USV-AUV) Collaborative Exploration with Energy Replenishment.” (Peer-reviewed)** Explores **heterogeneous swarm coordination**, extending aerial swarms to work jointly with unmanned surface and underwater vehicles. The authors present a dynamic programming approach to decide the optimal mix of drones, surface vessels, and underwater drones for a mission, given each platform’s speed and battery/endurance (including mobile charging stations)[14]. A genetic algorithm then plans coverage paths for the multi-vehicle team, and Dijkstra’s algorithm helps route them around obstacles (like islands or reefs) to ensure UAVs can periodically recharge without human retrieval[14]. Although primarily a simulation study, it indicates that *systems-of-systems* thinking (air, sea, sub-sea robots in concert) is already at play. This broadens the value proposition of drone swarms (e.g. a UAV swarm relaying data to an autonomous boat) and shows technical feasibility of coordinating different robot types – a capability likely necessary for truly scalable, long-term autonomous operations in the next decade.
- **UK Ministry of Defence (Dstl) – Press Release (May 2023): “World first as UK hosts inaugural AUKUS AI and autonomy trial.” (Official trial report)** Describes a **tri-nation field trial** where AI-enabled drones from the UK, US, and Australia were networked into a collaborative swarm that autonomously detected and tracked military targets in real time[15]. Notably, the swarm AI was flexible: during the exercise, the drones’ machine-learning models were *re-trained on the fly* and models were shared among partner nations’ drones, a world-first achievement[15]. This indicates a high level of swarm autonomy and adaptability in an operational environment. The success of this trial – part of the AUKUS defense pact’s advanced capabilities program – demonstrates rapid progress toward militarily viable swarms. It also highlights that multiple countries are now actively testing swarm robotics for practical use, which implies both technological maturity (at least at prototype level) and strong institutional investment.
- **Auterion (industry) – Autonomy Global News (Jan 2026): “Swarm Forge: Auterion Powers First Kinetic Live Swarm Strike on US Soil.” (Vendor technical news)** Documents a landmark **live-fire demonstration** conducted with the U.S. DoD: a single human operator successfully commanded a swarm of 3 autonomous drones to simultaneously strike 3 separate targets with explosive warheads[16]. The drones, equipped with Auterion’s open-source “Skynode” autopilot and swarm AI, coordinated their flight paths, avoided conflicts, and hit all targets under software control – proving a true “one-to-many” combat capability in a realistic scenario[16][17]. The demonstration validates that one operator can wield a coordinated attack by multiple drones, a clear advantage over the traditional one-drone-per-pilot model. In the same report, Auterion’s CEO notes “the one-pilot, one-drone model is obsolete”[18], and it’s revealed that **over 30,000** of Auterion’s swarm-capable autopilot kits have been shipped to Ukraine[19], indicating scaled deployment. Together, this is strong evidence of both engineering feasibility and a fast-moving path to real-world use, at least in defense contexts.

- Lockheed Martin & Verizon – 5G Drone Swarm Trials (C4ISRNet, Sep 2022): (Industry/Gov test report)** Describes joint tests where a *swarm of drones* equipped with ISR (intelligence, surveillance, reconnaissance) sensors were linked via **5G networks**[20]. In May and Sept 2022 demos, the drones were able to securely share real-time video and signals data over a private/public 5G, and an AI analytics system fused the data to detect and geolocate very low-power radio frequencies (simulating enemy communications or jamming devices)[20][21]. Army and Air Force observers noted the ability of 5G to handle the high bandwidth and low latency needed for swarm coordination. This demonstrates that existing telecom infrastructure (5G) can be leveraged to network drone swarms, enhancing their sensing range and reliability. It also showed a concrete battlefield application (electronic surveillance) where a multi-drone system outperforms a single platform. The success of these trials is a positive sign for the *scalability* of swarms – suggesting that as 5G/6G networks roll out, swarms could operate with robust connectivity and without deploying bespoke communication hardware.
- Shield AI – Tech Demo via AFWERX (Potomac Officers Club, Aug 2023): (Industry press)** Reports that Shield AI's autonomy software (*Hivemind*) piloted a **3-drone team of “V-BAT” UAVs** in a demonstration for the U.S. Air Force[22]. The drones worked together to detect, identify, and track objects during a simulated wildfire scenario, without GPS or constant comms – showcasing multi-UAV teamwork in a communications-denied environment[22]. This demo was the capstone of a U.S. AFRL program, and according to Shield AI it put their system on track for operational deployment of drone swarms by 2024. Shield AI (a well-funded startup) and others like it are in a competitive race to deliver deployable swarms for military use. The fact that the **same autonomy** (*Hivemind*) has also been flown on different platforms including quadcopters and even a fighter jet, reflects a push toward software-defined capabilities for swarms. This is evidence that multiple actors are refining the technology from prototype stage toward field-ready products, indicating a maturation from experimental to pre-production phase.
- Exyn Technologies – Field Deployment Case (Aug 2022): “Autonomous Cavity Monitoring in a German Salt Mine.” (Vendor field report)** Documents a commercial *multi-mission autonomous drone deployment* in an operating mine. Over three days, Exyn's drones flew **multiple fully autonomous flights** into large, hazardous underground cavities to map them, capturing high-resolution 3D point clouds **in a fraction of the time** of conventional survey methods[23]. Critically, this was done with no GPS and no human pilot in the mine – the drones made all navigation decisions and avoided obstacles (e.g. wires, narrow openings) on their own[24]. While these flights were one drone at a time (not a simultaneous swarm), Exyn's system is designed for one operator to supervise sequential autonomous missions. The success illustrates the growing *real-world adoption* of high-autonomy aerial robots in industry. It validates that the autonomy and sensor tech developed for swarms also delivers value with single drones today (e.g. improving safety and efficiency in mapping), and lays groundwork for near-future scenarios where **multiple such drones could operate concurrently** to further boost productivity.

### 3. Maturity score (1–7) and reasoning

**A) Maturity Score: 5** (on the 1–7 scale for the overall “Drone Swarms & Aerial Robots” technology bundle).

**B) Justification:** The evidence shows that drone swarm technology has progressed well beyond theoretical models (Levels 1–2) and lab prototypes (Level 3). **Working prototypes and PoCs (Level 4)** have been **successfully demonstrated in demanding real-world environments** – for example, fully autonomous multi-drone navigation through a dense

forest[1][2], and a 3-UAV team performing target searches without GPS[22]. These achievements prove that the once-“blocking” challenges (like inter-drone collision avoidance, decentralized mapping, etc.) can be solved in practice, meeting core functionality requirements. Furthermore, multiple projects have shown clear **benefit over single-unit operations**, such as faster area coverage and reduced risk to humans[23]. This satisfies much of Level 4.

Importantly, we now see **several well-capitalized actors racing to develop production-grade swarm systems**, which is characteristic of **Level 5** maturity. Evidence for this includes: **competition in the defense sector** (e.g. Shield AI, Auterion, Lockheed, and others are actively testing swarm capabilities[16][22]) and **significant government programs** (NASA, Dstl, DARPA, etc.) funding swarm R&D[8][15]. There are also initial signs of commercialization – for instance, Auterion shipping thousands of swarm-enabled drone kits to an active conflict[19], and Exyn selling autonomous drones to mining clients – indicating that prototype solutions are moving towards deployment and scaling. The **pace of progress is rapid** and recent: the first live-fire swarm strike was achieved just now in 2026[16], and multiple field trials in 2022–2023 broke new ground (AI swarms re-planning on the fly, multi-UAV wildfire monitoring, etc.). All this rules out Level 4: we are *beyond* a single proven PoC; rather, there’s momentum in turning prototypes into operational products.

At the same time, the technology hasn’t yet reached full **Level 6** commercialization where products are widely delivered to many customers with growing demand. Current deployments are **niche or pilot** in nature – e.g. military experiments, one-off emergency response demos, or confined industrial use with one-drone-at-a-time. Civilian regulatory constraints (one operator per swarm requires special waivers[7]) and unresolved issues like limited endurance still **prevent mass rollout** or routine everyday use. We have not seen broad adoption across industries or truly “increasing amounts” of swarm units purchased commercially (outside military urgent needs). Thus, the evidence does *not* yet show multiple competing off-the-shelf swarm products being adopted at scale – which would be needed for Level 6.

In summary, **Level 5** best fits the overall maturity: **drone swarms are in the late-prototype to pre-production stage**, with intense development activity and early customers in specialized markets, but not yet a ubiquitous product.

**C) Sub-component variation:** This ART encompasses several aspects (military swarms, civilian autonomous inspection drones, heterogeneity, etc.) that are maturing at slightly different paces. For instance:

- *Military lethal drone swarms* – rapidly advancing with substantial investment, arguably approaching early Level 6. The live swarm strike demo and large orders for swarm tech[19] show that defense customers are beginning to acquire these capabilities now.
- *Civilian swarm applications* (like firefighting, infrastructure monitoring) – closer to Level 4–5. We see convincing prototypes (e.g. the FireMan project’s semi-autonomous wildfire scouting in tests[13][25]), but regular commercial services are still a few years out, awaiting regulatory and safety milestones.
- *Enabling technologies* (autonomy algorithms, comm networks) – largely at Level 5: recent breakthroughs (e.g. robust decentralized mapping[3], 5G-enabled control[20])

solved key hurdles and are being integrated into trial systems now, but further refinement and validation are in progress.

Given these differences, **the chosen score 5 reflects an average** of the bundle. The core functionality – autonomous multi-drone coordination – is essentially proven (warranting >4), and in certain domains we see near-term transition to product delivery (pushing toward 6). But until the technology achieves routine use under broad conditions (which would merit 6) across its variants, Level 5 is the appropriate overall assessment. This level is reinforced by strong evidence of ongoing fast-paced development and competitive investment, which are hallmarks of a technology on the cusp of widespread commercialization.

## ART 05.031 Humanoid and General-Purpose Robots

### 17. ART extraction

18. **Primary capability:** Robots with a human-like form and dexterity that can operate in human environments and use human tools autonomously. They navigate spaces built for people (doors, stairs) and perform a wide range of tasks from physical labor to precise manipulations, reducing the need for constant human presence.

### 19. Key sub-components/variants:

- *Locomotion & Mobility:* Bipedal/legged platforms with agile walking, running, stair-climbing, and dynamic balance (e.g. Boston Dynamics' Atlas[1], Agility's Digit). Some designs use wheels or hybrid mobility for efficiency.
- *Manipulation & End-Effectors:* Multi-DOF arms and multi-fingered hands with force/tactile feedback for human-level object handling. Advanced prototypes have ≥11–20 DoF hands (e.g. Sanctuary's Phoenix has 20-DoF hands with haptic sensors[2]; Tesla Optimus Gen2's hands grew from 11 DoF to 22 DoF in one year[3]).
- *Sensing & Perception:* Rich sensor suites – stereo/RGB-D vision for 3D mapping, IMUs, force/torque sensors, often LIDAR[4]. Onboard perception builds real-time 3D models and recognizes people/objects. Some incorporate large vision-language models (e.g. Figure 02 has six RGB cameras and a vision-language model for visual reasoning[5]).
- *AI, Autonomy & Learning:* Onboard and networked AI for task planning, environment mapping, and human-robot interaction. Robots can take high-level instructions (speech or gestures) and learn new tasks via demonstration or simulation training. Notably, generative AI and LLMs are being integrated for higher-level reasoning and dialogue (e.g. Sanctuary's Phoenix uses a cognitive AI system with ChatGPT for understanding commands[6]; Figure 02 uses OpenAI's tech for natural language conversation[7][5]).
- *Human-Robot Interaction & Safety:* Interfaces for commanding robots include voice, wearables, and standard APIs. Safety-rated controls limit force and unsafe motions around people. Efforts are underway to develop ISO safety standards for legged robots[8]. Early deployments keep humanoids in controlled or isolated tasks to mitigate risk[9].
- *Power & Endurance:* Battery technology and power management are critical constraints. Current humanoids typically run 1–2 hours per charge[10], though

rapid charging or battery swapping is in development (Agility's next-gen Digit has a battery "backpack" giving 90 min runtime and a 9 min full recharge[11]). Most cannot yet work an 8-hour shift continuously; managing downtime and charging logistics in deployments is an active challenge[12][13].

- **Production & Cost:** Early units are complex and expensive (comparable to luxury vehicles or industrial machines). Scaling production involves securing supply chains for high-torque actuators, sensors, batteries, etc. Companies are investing in dedicated factories (e.g. Agility Robotics' new Oregon "RoboFab" can scale to >10,000 humanoids per year[14]). Simpler or smaller variants (e.g. 47 kg, 180 cm "Unitree H1" in China) trade off capability for lower cost[15].

20. **Maturity indicators:** Evidence of **working prototypes and field trials** (robots performing non-trivial tasks in real-world or mock-industrial settings) and **early commercialization efforts**. Key indicators include: multi-function demos beyond lab conditions (e.g. handling objects, tool use, navigating clutter)[16]; **pilot deployments** in workplaces or public environments (with safety measures)[17]; **investments in production** (factories, supply chain scaling, pre-orders)[14][18]; **multiple competing actors** (big tech, startups, government programs) advancing the technology in parallel[19]; and any **initial product sales or deliveries** to paying customers (even in limited volumes, as a step toward broader adoption). Evidence of improving cost-performance (e.g. runtime, payload, reliability) and concrete roadmaps for scaling up manufacturing would also signal maturity.

## 21. Evidence (10–20 recent, reliable sources)

22. **Agility Robotics opens factory for mass-producing humanoids** – Agility Robotics (press release) – Sep 2023[14][18]. Describes the launch of "RoboFab," a 70,000 sq ft facility in Oregon capable of building over 10,000 bipedal Digit robots per year. Agility anticipates "hundreds" of Digits produced in the first year and first deliveries to pilot customers in 2024, with general availability in 2025. This marks the transition from prototypes to production scaling, a pivotal step for commercial maturity.
23. **Humanoid Robots Aren't Scaling (yet)** – IEEE Spectrum (feature by E. Ackerman) – Sep 2025[19][20]. Analyzes the emerging humanoid industry boom: multiple well-funded companies (Agility, Tesla, Figure, etc.) plan aggressive production – e.g. Agility expects to ship hundreds of Digits in 2025 and built a factory for >10k/year[21]; Tesla aims for 5k Optimus in 2025 and 50k in 2026[22]. However, it notes current deployments are only "small handfuls" of robots in controlled pilots[23], and identifies key hurdles (battery life, reliability, safety) that must be solved before thousands of units can be truly useful[20]. This highlights both fast-paced progress and the gap to real-world scale.
24. **NASA's Valkyrie humanoid deployed for offshore facility tests** – NASA/Johnson Space Center (news release) – Jul 2023[24][25]. Reports a NASA project sending a Valkyrie humanoid robot to Western Australia under a partnership with Woodside Energy. The goal is to develop remote dexterous manipulation for maintaining uncrewed offshore oil & gas facilities[24]. NASA engineers delivered Valkyrie and trained Woodside staff, and the robot will be tele-operated to perform inspection and maintenance tasks in a hazardous, real-world environment[25]. This is a field trial by a government lab to mature humanoid capabilities for industrial use and gather data on performance outside the lab, underscoring the plausibility of humanoids in remote, dangerous jobs.
25. **Sanctuary AI's general-purpose humanoid in commercial pilot** – SiliconANGLE (tech news) – May 2023[2][26]. Describes "Phoenix," a humanoid robot (170 cm, 70 kg) launched by Canadian startup Sanctuary AI. Phoenix has 20-DoF hands with haptic feedback and can carry

25 kg, with a top walking speed ~4.8 km/h[2]. It runs on the company's "Carbon" AI control system (which integrates modern AI including GPT-based models) and is designed for "labor-as-a-service" work. The article notes a successful pilot where an earlier prototype completed 110 different tasks (about 40% of all tasks performed by staff) during a week-long trial in a retail store (Mark's, in Canada)[26]. This demonstrates a humanoid performing a broad task repertoire (stocking, cleaning, tagging, etc.) in a real commercial environment, indicating technical feasibility of general-purpose function and providing early evidence of value (freeing workers for higher-value tasks).

26. **Figure 02 humanoid: AI integration and BMW partnership** – Popular Science – Aug 2024[27][28]. Covers Figure AI, a well-funded US startup, and its second-generation humanoid Figure 02. The Figure 02 (a 5 ft 0 in, ~60 kg biped) has five-fingered hands (16 DoF) with "human-equivalent strength"[29] and a 2.25 kWh battery for ~7.5 hours runtime[28] – a 50% improvement over their first model. Figure 02 is equipped with OpenAI's language models for voice dialog and vision processing (six onboard cameras), enabling it to converse with humans and perform visual reasoning on the fly[7][5]. The piece notes that multiple Figure 02 units were tested at a BMW car factory moving automobile parts on an assembly line, as part of a pilot partnership[30][31]. While the demo tasks (carrying and positioning parts) remained relatively scripted, the integration of advanced AI and a real factory pilot highlight rapid advances toward autonomous, interactive robots in industrial settings.
27. **Rapid learning of complex tasks via human-in-the-loop AI** – Science Robotics (via UC Berkeley press/TechXplore) – Aug 2025[32][33]. Researchers at UC Berkeley demonstrated a training system (HiL-SERL) that enables robots to master complicated, multi-step tasks within 1–2 hours of real-world practice[34]. By combining human feedback (corrective teleoperation) with reinforcement learning, their robot achieved 100% success on challenging manipulation tasks like "Jenga block whipping," flipping a fragile egg, assembling a shelf and a car's dashboard, and even inserting chips on a motherboard[33][35]. This represents a major leap in robot skill acquisition, reducing the demonstrations or time needed by ~85–90% compared to earlier methods. Such progress in fast, robust learning algorithms makes it more plausible that general-purpose humanoids could be taught new tasks on the fly (or update their skill libraries remotely) – a critical aspect of the ART's vision.
28. **Xiaomi's "CyberOne" humanoid prototype** – IEEE Spectrum (news by E. Ackerman) – Aug 2022[36]. Reports that Chinese tech giant Xiaomi unveiled CyberOne, a full-size bipedal humanoid robot as a technology demo. CyberOne stands 177 cm tall, 52 kg, with 21 degrees of freedom and a curved OLED "face" display[36]. Xiaomi equipped it with vision and environmental sensors (it can create 3D maps and purportedly recognize human emotions), but acknowledged it as an R&D showcase rather than a near-term product[37][38]. The significance is that major companies globally (China, in this case) are investing in humanoid robotics, leveraging their manufacturing prowess. CyberOne's debut, while not delivering new functionality, underscores worldwide interest and the engineering feasibility (a consumer electronics firm built a functioning humanoid in-house) – though also illustrating that practical utility and durability remain hard, as noted by the skeptical tone of experts[39].
29. **Boston Dynamics' Atlas robot demonstrates tool use and agility** – New Atlas (tech review) – Jan 2023[16][1]. Describes the latest feats of Atlas, a cutting-edge humanoid from Boston Dynamics. In a 2023 demo, Atlas (1.5 m tall, 89 kg, 28 hydraulic joints[40]) was tasked with assisting at a mock construction site. It autonomously picked up a plank to bridge a gap, carried a heavy tool bag up stairs and across the plank, then threw the bag to a higher level – all while maintaining balance – and finally performed an inverted 540° aerial flip off a platform[16]. Engineers noted the flip pushes "the limit of what the robot can do"[41]. This showcases state-of-the-art locomotion and manipulation: dynamic balance, coordination under load, and

*whole-body motions that were purely aspirational a few years ago. Atlas is not a commercial product, but its technical achievements validate feasibility for many human-like movements (jumping, lifting, tool use), albeit with expensive hardware and still limited operating time.*

30. **Tesla's Optimus humanoid: from prototype to production plans** – SmartBot (academic review) – Mar 2025[42][43]. Summarizes milestones of Tesla's Optimus (also called Tesla Bot). A first prototype shown in 2022 (approx. 173 cm, 56 kg) performed basic tasks like walking, watering plants, and carrying small objects[42]. By 2023, Optimus "Gen 2" achieved stable walking in Tesla's factory environment and could remain balanced while lifting or manipulating objects[44]. It uses Tesla's self-driving vision algorithms for perception and navigation, and Tesla has publicly stated plans to deploy Optimus at large scale in industry, services, and homes[45]. Indeed, Tesla projects building thousands of units in the next couple of years (internal communications and investor events in 2023–24) – an ambition backed by its new dedicated robotics teams and heavy investment. No independent field data is available yet, but the presence of a major automaker committing resources to humanoids (including custom actuators and AI chips) and iterating prototypes quickly is a strong indicator of maturity: it suggests the concept has moved out of research and into serious development, with an eye toward cost reduction and manufacturability (Tesla aims for a sub-\$30k unit price in the future, akin to a car[46]).
31. **General progress and global efforts (academic review)** – SmartBot journal (Sheng et al.) – 2025[47][15]. A comprehensive review notes that many actors worldwide are now in the humanoid race. In the US, startups like Figure (which showed a humanoid making coffee and tidying objects) are integrating large-language models for instruction following[48]. In China, multiple universities and companies have prototyped humanoids: e.g. Unitree unveiled an 180 cm, 47 kg humanoid (H1) in 2023 that can run and climb stairs, and a smaller 127 cm version with a dexterous 3-fingered hand in 2024[15]. Established robot firms like UBTECH released the Walker biped that walks and navigates autonomously in indoor spaces[49]. Even auto companies (Xpeng, Xiaomi) and appliance makers (Fourier, Dreame) have revealed humanoid designs[50]. This breadth of R&D, spanning academia, government, and industry across North America, Asia, and Europe, reinforces that the core technical barriers are being addressed, and there is a consensus that general-purpose humanoids are within reach – driving a competitive, well-funded environment.

### 32. Maturity score (1–7) and reasoning

#### Proposed Maturity Score: 5 (out of 7).

**A) Justification of score:** The evidence shows that humanoid/general-purpose robots have **passed the proof-of-concept stage (Level 4)** and are now in an **early commercialization and scale-up race**. Multiple well-capitalized companies and research teams have working prototypes that solve key functionality challenges (dynamic bipedal walking, basic manipulation, autonomous navigation) beyond what earlier robots could do. For example, Tesla Optimus and Sanctuary's Phoenix have demonstrated stable locomotion and useful task execution (e.g. picking and placing objects) in real settings[44][26] – this rules out Levels 1–3, which correspond to mere theory or isolated lab demos. **Level 4** is also exceeded: we have *full-scale prototypes meeting many commercial requirements*. Agility's Digit, Figure 02, and others show **human-sized robots performing industrial tasks** with reliability sufficient for pilot deployments[26][31]. Critically, the step to **Level 5** is evident in the rapid progress toward production: Agility Robotics opening a factory for mass-producing Digits[14], Tesla planning thousands of units[51], and multiple startups (Figure, 1X, Apptikon, etc.) raising significant funding to build the first market-ready humanoids. There is clear *competition*

among well-funded actors to develop production prototypes, which is the hallmark of Level 5. Progress is fast-paced, with successive prototype generations in 1-year cycles and improving capabilities (e.g. Optimus Gen2 to Gen3 within a year, doubling hand DOF and adding capabilities[3], and Figure going from a rough Version 01 to an AI-equipped Version 02 in ~18 months[27]).

**B) Why not a higher score?** We stop short of **Level 6 (products delivered in increasing volumes)** because true commercial rollout is only just beginning. **Few robots have been delivered to paying customers** so far – deployments are mostly pilots or internal tests (e.g. Sanctuary’s 110-task trial at a store[26], NASA’s single Valkyrie at an oil facility[24], a few Digits to research partners). No company yet has hundreds of humanoids performing daily work for customers in the field – the market remains “almost entirely hypothetical” at scale[23]. Moreover, key practical hurdles like battery endurance, safety certification, and long-term reliability are still being worked out (e.g. ensuring <1% downtime in factories[13], and drafting new ISO safety standards for legged machines[8]). Economic viability is not proven at scale – although unit costs are projected to fall with volume, currently these robots are expensive bespoke systems. Thus, while **the trajectory toward Level 6 is clear** (with initial manufacturing capacity now in place[14] and large pre-orders envisioned[22]), the **evidence of actual scaled adoption is not yet present**. Reaching Level 6 will require seeing dozens-to-hundreds of humanoids reliably working in industry, which is likely a couple of years away.

**C) Sub-component breakdown:** This ART combines several subsystems at different maturity levels, but they coalesce into one integrated product (the humanoid robot). Key sub-elements:

- **Mobility (locomotion & balance):** *Maturity*  $\approx$  4–5. Robots like Atlas and Digit have demonstrated human-comparable mobility (running, jumping, uneven terrain) in demos[1][52], solving many research obstacles. The remaining gap is hardening these capabilities for low-cost, everyday use (current systems are expensive and can still fail in unstructured settings).
- **Manipulation (arms & hands):** *Maturity*  $\approx$  3–4. Sophisticated robot hands exist (20+ DOF with touch sensing[2]), and recent AI advances let robots perform complex manipulations (assembly, tool use) with high success rates[33][16]. However, real-world robustness and human-level dexterity (especially for tiny objects or high precision) are still emerging. Many humanoids use relatively simple grippers or limited-finger hands in practice for reliability.
- **Autonomy & AI:** *Maturity*  $\approx$  4. There’s been striking progress in cognitive capabilities – vision, planning, and learning. Robots can follow voice instructions and learn new tasks from one demo or a few hours of training[34][7], which was infeasible until recently. Yet, *general* autonomy (the ability to adapt to arbitrary new tasks and environments with minimal help) is not fully achieved; most deployments require structured tasks or human oversight (teleoperation or engineers on call).
- **Power and hardware reliability:** *Maturity*  $\approx$  3. This is a limiting factor: current battery tech yields ~1–2 hours of work per charge[10], and frequent charging or swapping is needed for continuous operation[53]. High-performance actuators tend to heat up or wear, and maintenance needs in 24/7 settings are unproven. Efforts like quick-charge batteries[54] and efficient all-electric designs are underway, but field reliability over months/years is not demonstrated.
- **Manufacturing & cost:** *Maturity*  $\approx$  5. Surprisingly, this aspect is being tackled head-on now:

Agility's factory and Tesla's planned production indicate that building thousands of units is viewed as *feasible with existing supply chains* (they note humanoids can leverage supply chains of industrial arms and EVs)[55]. **Investment and scaling plans are in place**, even if the market demand side is uncertain[56].

Given these sub-scores, the overall maturity is around **4+**, but we weight the higher end because the *integrated system* is what defines the ART's impact. The various subsystems are rapidly converging into viable products due to the intense engineering efforts currently underway. The **presence of multiple competitors and active prototypes tips the scale to a solid Level 5** – the project is beyond proof-of-concept, firmly in the stage of refining prototypes into products, with clear momentum toward initial market entry. In summary, humanoid/general-purpose robots are **plausible and partially demonstrated (Level 4)** and are now **on the cusp of real-world deployment with major backing (Level 5)**, but **not yet broadly adopted or proven at scale (not Level 6)**.

## ART 05.032 Soft Robotics & Bio-Inspired Machines

1. **ART extraction**
2. **Primary capability:** Enables robots with deformable, compliant bodies that safely interact with fragile objects, humans, and tight or cluttered spaces by mimicking the soft movement and adaptability of biological organisms. These soft robots can absorb impacts and conform to their environment, performing gentle manipulation or navigation tasks that would damage or trap conventional rigid robots.
3. **Key sub-components or variants:**
4. *Soft structures & materials:* Flexible polymers, elastomers, gels, textiles, and composites form the robot's body and joints, allowing it to bend, stretch, and squeeze as needed.
5. *Bio-inspired actuators:* Fluidic or pneumatic networks and "artificial muscle" actuators (e.g. air muscles, electroactive polymers, shape-memory alloys) produce motion without hard skeletons, often inspired by muscle or hydraulic systems in animals.
6. *Distributed soft sensors:* Flexible tactile and strain sensors embedded throughout the robot detect pressure, texture, force, or shape changes, feeding data to on-board controllers.
7. *Embedded control & AI:* On-board processors run real-time control algorithms that use data-driven models and bio-inspired gait/grasp patterns. Robots can learn motions via imitation of human demonstrations or reinforcement learning, simplifying programming.
8. *Human-friendly interfaces:* Instead of manual joint-by-joint coding, users can command the robot through high-level APIs, voice or gesture controls, making operation intuitive (the robot's "mechanical intelligence" handles low-level coordination).
9. *Specialized fabrication:* New manufacturing methods (soft lithography, multi-material 3D printing, fabric weaving of actuators) enable scalable production of complex soft robotic components, though requiring specialized tools and materials.
10. *Variants:* Soft robotic grippers and manipulators (for gentle picking in factories or agriculture), wearable soft exosuits (assistive apparel for human mobility or rehabilitation), soft mobile robots (e.g. snake-like or vine robots for search-and-

rescue, soft drones or underwater vehicles for exploration), and hybrid rigid-soft systems that combine a firm base with soft end-effectors.

#### 11. **Maturity indicators:**

12. Field demonstrations of soft robots performing tasks in real-world conditions (e.g. factory lines, disaster sites, medical trials), showing they can reliably operate outside the lab.
13. Functional prototypes solving previously intractable problems (gentle handling of delicate food, navigating collapsed buildings, assisting human gait) and meeting key performance benchmarks (speed, force output, endurance) beyond what human workers or rigid bots can achieve.
14. Early commercial products and startups: e.g. soft gripper tools being sold and deployed in industry, or soft exosuits entering pilot clinical use – indicating progress from research to market.
15. Investment and competition: multiple startups and major firms (robotics companies, automation suppliers) developing soft robotics solutions, significant venture funding or corporate R&D programs, and emerging industry consortia/standards (including safety certifications for robots working near people).
16. Signs of scalable manufacturing and maintenance: development of durable materials (e.g. self-healing or fatigue-resistant elastomers) and modular designs, as well as training programs or documentation that allow broader adoption by non-experts.
17. **Bottlenecks to watch:** improvements in actuator power-density (for faster, stronger motion untethered), longer material lifespan (fatigue, tear resistance), portable power sources, and formal safety testing – progress on these will mark readiness for wide deployment.

#### 18. **Evidence (10–20 recent, reliable sources)**

19. **Festo HPSX Soft Gripper** – *Festo (vendor technical doc, 11/2023)* – Industrial automation company Festo released the **HPSX soft gripper**, a hygienic, food-grade gripper with soft modular silicone fingers. It comes in three sizes and can gently handle items from strawberries to melons without damage. The design’s soft compliance and ISO-standard robot mount make it easy to integrate on collaborative robots, addressing delicate handling needs in food, pharmaceuticals, and cosmetics[1][2]. (This shows a commercial soft robot end-effector meeting industry safety and cleanliness standards.)
20. **Soft Robot Tech (SRT) soft grippers** – *SRT company profile (China, 2023)* – Beijing-based startup SRT, founded 2016, reports its **soft robotic grippers** can mimic human hand motions to grasp ~96% of object shapes encountered in industry[3]. SRT claims over **500 customers worldwide across 30+ countries**, deploying soft grippers in fresh food handling, electronics assembly, semiconductors, agriculture, rehabilitation devices, etc.[4]. (This indicates significant early commercial adoption of soft robotics, with broad industry and geographic reach.)
21. **Soft Robotics mGrip in produce packing** – *Photonics Spectra (trade magazine, Winter 2022)* – Describes an automated packing line for sweet potatoes where a **Soft Robotics Inc. “mGrip” soft gripper** was installed to handle produce of varying shapes[5]. Competing rigid grippers struggled with the irregular produce, but the pneumatic mGrip fingers (made of food-safe elastomer) gently grasp items without manual tuning. After integration, the system saw immediate improvements – even delicate baked goods could be picked “without breaking them,” which was previously impossible[6]. A 3D vision system guides the soft gripper to consistently fill boxes, eliminating labor-intensive packing and product damage.

(Demonstrates a real-world deployment where soft robotics outperformed conventional automation in gentle handling and adaptability.)

22. **Soft Robotics mGripAI commercial adoption** – *NVIDIA Blog (01/2023)* – Reports that **Soft Robotics (USA)** has developed the mGripAI system (soft grippers + 3D vision + AI) for food processing lines[7]. Major food companies like Tyson Foods and Johnsonville are using this technology to pick and place meats and produce at high speeds (up to 100 picks/min) without bruising or contamination[8]. The company received **\$26 M Series C funding** led by food industry investors to scale up production[9], and its tools are helping alleviate labor shortages and injury risks in poultry packaging. (Shows that soft robotic solutions have progressed to **scaled industrial pilots and attracted substantial investment**, meeting throughput demands in a billion-dollar sector.)
  
23. **EU–Japan “CURSOR” rescue robots** – *Horizon Magazine (EU R&I, 06/2025)* – Describes the **SMURF (Soft Miniaturised Underground Robotic Finder)** developed in a 2019–2023 EU-Japan project for disaster search-and-rescue[10]. This small two-wheeled soft robot carries cameras, two-way audio, and a chemical sensor “SNIFFER” that detects human breath markers (CO<sub>2</sub>, ammonia). In field simulations, multiple SMURFs could be **deployed into rubble via drones** to locate trapped survivors while keeping first-responders out of harm’s way[11]. The SMURF’s **chemical sensor proved reliable amidst smoke and rain**, distinguishing live victims from remains[12]. (Evidence of a successful **prototype field trial**: soft robots with advanced sensing functioning in unpredictable, hazardous environments, highlighting both feasibility and remaining challenges before real deployment.)
  
24. **MIT’s SPROUT vine robot** – *TechXplore/MIT News (04/2025)* – Researchers at MIT Lincoln Lab and Notre Dame demonstrated **SPROUT**, a “vine” robot for urban search-and-rescue[13][14]. SPROUT is an **inflatable soft robot** that “grows” a flexible tube through debris by air pressure, allowing it to maneuver around obstacles and snake through narrow voids. It can currently extend ~10 feet (aiming for 25 ft) and is teleoperated via a simple joystick interface[15]. The team solved challenges in controlling the robot’s deformable body (steering via internal air pressure, minimizing friction) so that first responders can deploy it without expert knowledge[16]. (This prototype addresses the key **niche of navigating confined, unsafe spaces**, and is being developed with user-friendly control for eventual field use by emergency personnel.)
  
25. **“WalkON” soft robotic exosuit** – *Tricomi et al., Nature Machine Intelligence (10/2024)* – A peer-reviewed study of **soft robotic shorts (exosuit)** that assist hip motion in walking. The device uses lightweight textile braces and cable/tendon actuators to add force during hip flexion. In outdoor tests, young adults walking uphill with the powered shorts expended **17.8% less energy**, and in a separate trial older adults on level ground saw a **~10.5% reduction in metabolic cost** while wearing the exosuit[17]. Participants maintained a high sense of natural control (rating ~6.1/7) over their gait. These results, achieved in real-world environments (hiking trail, outdoor track), show that soft wearable robots can **meaningfully improve mobility and endurance** for users, beyond laboratory settings. (Demonstrates a **proof-of-concept exoskeleton** nearing practical viability for assisting human locomotion, with comfort and efficiency gains.)
  
26. **Untethered soft actuator advances** – *Park et al., Nature Communications (2024)* – A comprehensive review of recent progress in soft robotics notes that while soft robots offer extraordinary compliance and safety, they historically suffer from **limited force output and reliance on tethers** (external pumps/wires for power)[18]. It highlights emerging solutions: e.g. **pump-free pneumatic actuators** using phase-changing fluids to generate pressure internally, and soft actuators driven by external stimuli like magnetic fields, light, or wireless

electricity[19]. Such approaches have demonstrated increased force and motion speed without bulky air hoses, inching soft robots toward fully untethered operation. (This underscores that the field has **moved beyond fundamental principles** – researchers are actively solving engineering roadblocks like power and force density, which is crucial for real-world deployment.)

27. **Durability testing of soft actuators** – Bui et al., *Frontiers in Materials* (05/2023) – Investigated the longevity and performance drift of a **silicone fabric-reinforced pneumatic actuator** under extended use. Through cyclic tests, the team found the actuator’s motion stabilized after an initial “break-in” (~160 inflation cycles) despite some hysteresis, and it withstood **over 1,280 actuation cycles** before failure in pressure tests[20]. This indicates current silicone soft actuators can operate through hundreds of cycles with repeatable performance, but also highlights the need to improve material fatigue life. (Provides empirical data on **soft robot reliability**, showing progress in understanding and extending the lifespan of soft components to meet practical service requirements.)
28. **Soft robot in the deep sea** – Li et al. via *Nature Communications* (11/2023) – Reports a breakthrough wherein a **soft robotic fish**, inspired by the deepest-living snailfish, was successfully tested at extreme ocean depth. The untethered robot, using dielectric elastomer “muscle” actuators and a soft body, survived pressures of **110 MPa (Mariana Trench depth)** without a rigid vessel[21]. It swam effectively in a pressure tank and achieved free-swimming at >3,000 m depth, even performing at **~10,900 m** in field trials. This world-first demonstration of a soft robot operating at such depth validates the approach of using compliant materials to withstand high pressure, and paves the way for gentle deep-sea exploration of fragile marine life. (Shows **scientific feasibility proven in extreme conditions**, a strong plausibility signal for soft machines where rigid ones fail.)
29. **SofaGym simulator for soft robots** – Schegg et al., *Soft Robotics journal* (04/2023) – Introduces “**SofaGym**,” an open-source platform that connects a physics-based soft robot simulator (SOFA) with the standard OpenAI Gym reinforcement learning interface[22]. The authors provide 11 example environments (different soft robot morphologies and tasks) and demonstrate how learning algorithms can be applied to optimize control and motion planning for soft robots[23]. By offering a common toolkit for training soft robotic control policies and easing sim-to-real transfer, this work lowers the barrier for researchers and companies to develop **intelligent, adaptive behaviors** in soft robots. (Evidence of ecosystem maturation – tools for simulation, learning, and programming are emerging, which will speed up development and deployment of soft robotics applications.)

### 30. Maturity score (1–7) and reasoning

**Assigned Score: 5 (Early commercial prototypes with growing investment and competition)**

**A) We score Soft Robotics & Bio-Inspired Machines as a 5**, reflecting an **intermediate maturity**: key proofs-of-concept have been demonstrated and several startups and industry players are actively pushing toward production and scale, but full commercial maturity in all areas isn’t yet achieved. Notably, **multiple well-funded actors** are involved (e.g. Soft Robotics Inc., SRT, Festo, plus academic spinoffs), and **early products** like soft grippers are on the market, which goes beyond a lab prototype (ruling out Levels 1–3). For instance, Festo’s and SRT’s soft grippers are being delivered to customers for gentle handling in factories[1][24], and Soft Robotics’ systems have secured significant industry funding for expansion[9], indicating we are past the one-off demo stage. This collective momentum

satisfies many Level 5 criteria: **proof-of-concept prototypes clearly solving real problems, with investment to commercialize and fast-paced progress** in recent years.

**B) Why not a 6 or 7?** The technology as a whole isn't fully at Level 6 because widespread production use is still *nascent and fragmented*. **Some sub-fields (like soft gripper end-effectors)** are approaching Level 6 – they have paying customers and scaling demand (500+ clients in SRT's case) – but other aspects remain in prototyping. For example, **soft wearable exosuits and soft mobile robots** are only in pilot testing or limited trials (e.g. the WalkON exosuit showed real-world efficacy[17] but is not yet a sold product, and vine robots like SPROUT are functional demos, not deployed equipment[15]). Fundamental technical gaps such as **power and durability** also persist: most soft robots still rely on external pumps or tethers and have lifespan issues[18][20], which companies are actively addressing but not fully solved. These gaps mean that, although demand is rising and niche adoption is underway, we have not seen **broad, off-the-shelf commercialization across the board** that would merit Level 6. To reach the next level, we would expect to see robust untethered soft robots operating at scale in multiple industries, formal safety certifications in place, and primarily internal (revenue-driven) R&D rather than grant-funded – evidence which is still emerging.

### C) Sub-component breakdown:

- **Soft grippers/manipulators (industrial automation):** *Maturity ~6*. They are **commercially deployed in production environments**. Companies like Soft Robotics and SRT have products handling food, electronics, etc., with hundreds of end-users[24]. Major firms (Tyson Foods, etc.) are investing in these for immediate operational use[9]. This segment sees **competition and early economies of scale**, inching toward Level 6.
- **Soft wearable robots (exosuits, medical devices):** *Maturity ~4*. Functional **prototypes have been validated in relevant scenarios** (assisting mobility with measurable benefits[17]). Some start-ups and collaborations (e.g. through rehabilitation trials) exist, but products are not widely available yet – they are at proof-of-concept/pre-commercial stage.
- **Soft mobile robots (search-and-rescue, exploration):** *Maturity ~3–4*. There are **working prototypes** (vine crawlers, soft rescue bots) demonstrating unique capabilities in field tests[10][14], which proves feasibility (Level 3). A few are moving toward advanced pilot demonstrations (bordering Level 4), but none are in routine practical deployment due to ongoing R&D on reliability, control and regulatory approval for use in safety-critical situations.
- **Core soft robotics technology (materials, actuators, control software):** *Maturity ~3*. The scientific principles are proven and there are many lab demos (Level 2 achieved long ago), and importantly some **previously blocking challenges have been partially solved in the lab** – e.g. new actuators without tethers[19], or soft robots surviving extreme conditions[21] (indicative of Level 3). However, many components are still in the optimization stage and not yet at a cost or robustness suitable for mass production.

Taking an **average view of these components**, the overall area stands at **Level 5**. We chose an average-based score because the “soft robotics” bundle spans diverse applications – from factory grippers to medical devices – that are maturing at different rates and largely serve different markets (the value is distributed across various use-cases rather than one unified product). **In summary, the strongest evidence (industrial adoption and multi-million-dollar investments) pushes the score above 4**, but full maturity is tempered by other sub-fields lagging behind. Achieving a solid Level 6 will require further convergence of

these advances: untethered operation, proven durability, regulatory safety frameworks, and profitable scale in more than one domain – all of which are in progress, but not uniformly realized yet.

## ART 05.033 Fully Autonomous Drones, Robots & Underwater Vehicles

### 33. ART extraction

**A) Primary capability:** The ART envisions robotic vehicles (drones, ground robots, underwater vehicles) that can operate *fully autonomously* in environments dangerous or inaccessible to humans. The key capability is long-duration, reliable sensing and manipulation in remote areas with **minimal human supervision**. These systems aim to maintain presence and perform tasks (inspection, transport, assembly) in harsh conditions where human operation would be risky or impractical.

### B) Key sub-components or variants:

- **Autonomous aerial drones (UAVs):** Uncrewed aircraft with advanced autopilots and on-board AI, able to take off, navigate, and land with little oversight. They carry modular sensor or cargo payloads for missions at high altitude or over long distances.
- **Autonomous ground robots (UGVs):** Wheeled, tracked or legged robots that can traverse challenging terrain (rubble, stairs, remote sites) on their own. Often designed with **modular bases** and attachable tools (arms, cameras) to perform inspections or manipulate objects (e.g. opening valves).
- **Autonomous underwater vehicles (AUVs):** Submersible robots with pressure-tolerant hulls, capable of deep or long-duration underwater missions without tether or constant contact. They use sonar, inertial navigation, etc., to map and operate in the ocean depths.
- **Sensor fusion & real-time mapping:** All variants rely on combining inputs (cameras, LiDAR/radar, sonar, IMUs, GPS or alternative positioning) to perform SLAM (simultaneous localization and mapping) in unknown or GPS-denied environments. High-powered onboard computing and AI enable them to build detailed maps on the fly and avoid obstacles or adapt to changes without human intervention.
- **Swarm coordination:** Many units can work in **fleets or swarms**, sharing data (maps, sensor findings) and dividing tasks. A small number of human operators can oversee a large autonomous fleet. Swarm algorithms and V2V communication allow cooperative behaviors (e.g. distributed surveying, target search) even if external comm links are lost.
- **Human-robot interaction:** Humans interact at a high level via dashboards, mission planning software, or even natural-language commands. The robots handle fine-grained control autonomously. Human input is supervisory (setting goals or checking status), rather than manual teleoperation in real time.

### C) Maturity indicators to look for:

- **Field demonstrations and deployments:** Evidence of these robots operating autonomously in real-world conditions (e.g. disaster sites, industrial facilities, polar regions, open ocean) for extended periods, performing useful tasks.
- **Prototype → product transition:** Reports of functional prototypes meeting key requirements (endurance, navigation, payload use) and moving toward commercialization – e.g. pilot programs, proof-of-concept trials, or initial products delivered to early customers.
- **Competitive development and investment:** Multiple well-funded companies, defense programs, or research consortia developing such systems (and, ideally, competing to

improve them), indicating a broad push toward scalable products.

- **Scaling and production metrics:** Signs of scaling up, such as **units produced or deployed**, manufacturing partnerships, or large pre-orders. Also, standards or certifications (for safety in shared spaces, explosion-proof operation, etc.) enabling wider use.

- **Performance milestones:** Concrete achievements that surpass traditional approaches – e.g. missions lasting days or weeks without human intervention, multi-robot cooperation in complex tasks, autonomous manipulation successes, or endurance in extreme environments (high winds, deep sea).

- **Regulatory and operational integration:** Evidence of regulatory approvals or waivers (like beyond-visual-line-of-sight flight waivers, autonomy in public spaces) and of end-user adoption (military or industry integrating these robots into regular operations).

#### 34. Evidence (10–20 recent, reliable sources)

35. **Autonomous cargo drone in extreme environment (British Antarctic Survey):** “*Ice World Exploration: Pilotless Uncrewed Aerial Vehicle Arrives in Antarctica*” – Press release, British Antarctic Survey – Feb 2024. [1][2] Describes field testing of the Windracers ULTRA, a fully autonomous twin-engine UAV (10 m wingspan) that carries 100 kg over 1000 km. It can take off, fly, and land with only minimal operator oversight using a patented autopilot. Built with redundancies for harsh conditions, it’s being trialed in Antarctica to extend scientific reach. The project also envisions deploying **multiple ULTRA drones as a coordinated swarm**, demonstrating feasibility of sustained autonomous operations in one of Earth’s toughest environments. This shows both the *plausibility* (rugged autonomous flight proven in the field) and emerging *maturity* (government-funded trial of a near-production system).
36. **Large-scale autonomous drone network for utility inspection (Percepto/FPL):** “*Percepto unveils world’s largest autonomous commercial drone deployment at leading US electric utility*” – Press Release, Percepto (drone-in-a-box vendor) – Apr 2022. [3][4] Florida Power & Light, a major utility, is deploying a network of autonomous “drone-in-a-box” units for statewide grid monitoring. Phase 1 rolled out 13 autonomous drones, with **hundreds more planned over five years**, making it the world’s largest commercial autonomous drone project. These drones live on-site in weatherproof docks, run missions beyond visual line of sight under an FAA waiver, and even withstood Level 5 hurricane winds in testing. This evidences *maturity*: a well-capitalized end-user moving beyond pilots to scale up autonomous drone operations (a strong indicator of level 5–6, with real deployments and regulatory integration). It also underscores the technology’s value in reducing manual inspections and emergency response time.
37. **AI-coordinated drone swarm with minimal comms (Airbus & Quantum Systems):** “*Airbus and Quantum Systems make progress in autonomous swarm technology*” – Joint industry press release (Airbus Defence & Space, Quantum Systems) – Aug 2024. [5] Reports a successful field test in Germany of **seven drones controlled by a single AI-driven mission system** as part of a defense research program. Heterogeneous UAS (fixed-wing and multirotor) were autonomously coordinated even under GPS jamming and communication loss. All drones’ sensor data were fused in real-time to form a common situational map, and the AI autopilots dynamically adjusted roles to complete reconnaissance and target-location tasks without direct human control. This demonstrates the *feasibility* of multi-robot autonomy at a tactical scale (each drone adapting to others and to degraded conditions) and indicates growing *technical maturity* in swarm control algorithms (relevant to the ART’s vision of swarm operation in harsh, comm-denied environments).

38. **Long-endurance autonomous underwater vehicle (Kongsberg, Norway):** “*Mission accomplished for the world’s first HUGIN Endurance*” – Vendor technical news (Kongsberg Discovery) – Mar 2024. [6][7] Announces that Kongsberg’s new HUGIN Endurance AUV (launched 2021) completed sea trials and was delivered to its first customer. This large AUV can operate **up to 15 days and 2200 km** on one mission, with modular payload bays for sonar, cameras, and environmental sensors. The first production unit passed factory and sea acceptance tests by early 2024 and demonstrated all capabilities to the customer. This marks a key *maturity milestone*: a formerly experimental long-range AUV is now a commercial product, meeting the endurance and autonomy requirements for real-world use (military and industrial interest is noted). The robust navigation and power systems needed for multi-week unsupervised operation at sea validate the ART’s plausibility in the underwater domain.
39. **Five-week fully autonomous undersea mission (UK research):** “*Autosub Long Range 1500: A continuous 2000 km field trial*” – A.B. Phillips *et al.*, *Ocean Engineering* (peer-reviewed) – July 2023. [8] Documents a record-breaking mission by the UK’s National Oceanography Centre: their Autosub Long Range 1500 AUV conducted a **5-week (2000 km)** unaccompanied deployment from Plymouth into the North Atlantic and back. The vehicle operated continuously beyond visual or communication range, using only half its battery capacity over 2000 km. This experiment demonstrates the *feasibility* of truly persistent autonomous presence underwater. Achieving multi-week autonomy, robust navigation in open ocean, and power management over such distance showcases that the core technical barriers (energy, navigation, reliability) can be overcome in practice. It pushes the platform toward operational readiness (between lab prototype and full production, i.e. ~level 3–4 maturity for this specific model).
40. **Extra-large unmanned submarine delivered to Navy (Boeing Orca XLUV):** “*U.S. Navy Accepts Delivery of First Extra Large Unmanned Undersea Vehicle*” – U.S. Navy PEO USC official news – Dec 2023. [9][10] The U.S. Navy took delivery of its first Orca XLUV “autonomous submarine” from Boeing, marking the transition from development to fleet integration. The Orca is a 15.5 m diesel-electric UUV with a modular payload section for different missions (e.g. mines, sensors). It is designed for **long-endurance autonomous operation**, carrying out undersea missions with minimal human contact. This event indicates substantial *maturity*: a decade-long R&D program culminating in an operational prototype now in the hands of an end-user (level 4→5). The Navy’s plan to field five Orcas, and the platform’s flexibility to adapt to new payloads, underscores both the commitment of a major institution and the plausibility of unsupervised vehicles performing complex tasks (critical undersea missions) reliably.
41. **Autonomous legged robots entering industry (ANYbotics, Switzerland):** “*World’s Only Scalable Ex-proof Robot Inspection Solution Now Available to Industry*” – Press release, ANYbotics – Sep 2022. [11][12] Announces the commercial launch of the **ANYmal X** quadrupedal robot – a fully autonomous, explosion-proof inspection robot for oil & gas facilities. The manufacturer opened orders after successful early deployments, highlighting that over **500 units were already reserved** by early adopters and production was being scaled with manufacturing partners. First customer deliveries began mid-2023. This shows a rapid move from prototype to production, with *strong market demand* in a niche (hazardous environment inspection). ANYmal X uses AI-based locomotion and navigation to climb stairs and traverse complex plants autonomously, tasks that fit the ART’s vision of robots in hard-to-reach or dangerous spaces. The volume of pre-orders and compliance with strict safety certifications (ATEX/IECEX for explosive atmospheres) signal a ~level 5–6 maturity for autonomous ground robots in industry (multiple units in real operation, supported by significant investment).

42. **Widespread deployment of quadruped robots (Boston Dynamics Spot):** “*Robot Police Dogs Are on Patrol, But Who’s Holding the Leash?*” – Undark (science magazine) – Sep 2023. [13] Reports that **over 1,000 Boston Dynamics Spot robots** were operating across 35 countries by 2022, according to a company blog post. Spot is a commercially available autonomous quadruped that can be teleoperated or run missions autonomously (e.g. routine patrols, data capture). This statistic provides concrete evidence of *scaling*: competing products in the autonomous robot space are being delivered globally in significant numbers. It underscores that the core technology is beyond the lab/prototype stage – real customers are investing in these robots for diverse applications (from power plants to police departments). Such multi-continent adoption and iterative product improvements (Spot has seen hardware/software upgrades) reflect a maturity level trending toward **6**, although full unsupervised use in public space remains limited by policy.
43. **Multi-robot autonomy in complex terrain (DARPA Subterranean Challenge):** “*Team CERBERUS Wins the DARPA Subterranean Challenge: Technical Overview*” – M. Tranzatto *et al.*, arXiv preprint (ETH Zurich, others) – July 2022. [14] Details the winning approach in a major robotics competition, where a team deployed a “**system-of-systems**” of **legged and flying robots** to explore underground tunnels and caves with no GPS and unreliable comms. The CERBERUS team’s robots leveraged sensor fusion and resilient autonomy to map and navigate perilous terrain, all while one human supervisor merely gave high-level commands. The robots could dynamically replan and overcome obstacles (like rubble or vertical shafts) without direct teleoperation. This is a compelling *feasibility proof*: it shows that multiple heterogeneous robots can autonomously coordinate to perform search and mapping in real time, exactly the kind of hard, unmapped environment envisioned by the ART. The success in DARPA’s challenge (final event in 2021, documented 2022) indicates the technology for robust autonomy exists at least at prototype level (TRL ~6 for that context), though transitioning this to everyday commercial use is ongoing.
44. **Drones autonomously building structures (Nature cover story):** “*New bee-inspired drone fleet works together to build 3D objects*” – UCL & Imperial College London, *Nature* (covered in UCL News) – Sep 2022. [15][16] Describes a research demonstration where **flying drones cooperatively 3D-printed a cylinder 2.05 m tall** (72 layers) and another structure out of cement-like material, all autonomously. A team of “BuilDrones” deposited material while “ScanDrones” measured progress; the drones adjusted their paths in real-time to ensure the structure met the blueprint specs. They required no human intervention during the build, aside from a monitoring operator. This achievement highlights the *versatility and precision* that modern autonomous robots can attain – not only navigating, but actively manipulating the environment (constructing or repairing structures). It reinforces plausibility for tasks like assembly or disaster-repair that the ART foresees. While this was a controlled experiment (≈ level 3–4, lab prototype), being published in *Nature* with plans to work with construction firms suggests a path toward field trials of autonomous construction swarms in coming years.
45. **Maturity score (1–7) and reasoning**

**Proposed Maturity Score: 6** (out of 7) – *Early commercial rollout and scaling.*

**A) Why not lower:** The collected evidence shows that we are well beyond theoretical or lab-only stages (levels 1–3). Multiple **working prototypes have been proven in demanding environments** – e.g. a 5-week undersea mission with no human contact[8], autonomous drones mapping Antarctic ice[1], legged robots performing industrial inspections[11]. In fact, several of these technologies have reached **Proof-of-Concept and productization stages (levels 4–5)**: for instance, the first Orca XLUV was delivered to the Navy in 2023[9][10], and

ANYbotics is fulfilling orders for dozens of ANYmal X units to oil & gas clients[12]. We also see **well-capitalized actors and competition** in each domain – from big defense contractors (Boeing, Airbus) to specialized robotics firms (Boston Dynamics, ANYbotics) – investing heavily and vying to deploy autonomous robots. These are strong signs that the field has progressed into the *production prototype and initial deployment phase*. Real customers are using the technology, validating its value by ordering more (e.g. FPL planning hundreds of drones[3]). This clearly rules out levels 1–4 and even level 5: we have moved beyond one-off demos and isolated prototypes to **small-scale commercial fleets and multi-unit deliveries** across different regions.

**B) Why not higher:** The overall ART spans multiple platforms (air, ground, underwater) which are each at slightly different maturity points – but none have fully achieved level 7 ubiquity yet. **Autonomous drones** for inspection and surveying are the closest to mature: thousands are in operation[13], and major expansions (like the utility deployment) are underway.

**Autonomous ground robots** (like quadrupeds) are a nascent market with hundreds of units being adopted in industrial settings[11], but they are not yet as common or trusted as, say, industrial vehicles. **Autonomous underwater vehicles** tend to lag a bit in volume – advanced models exist and have *just* started to see operational use (e.g. Kongsberg’s 15-day AUV in 2024), but these are still specialized deployments rather than widespread fleets. Moreover, *fully* unsupervised operation in open public environments remains limited by regulations and technical edge cases (safety, reliability under all conditions). For example, drones still often require special waivers for beyond-line-of-sight flight[17], and robotic trucks or ships aren’t yet driving among the general population without oversight. To reach **level 7**, we would expect to see *competing products in broad, rising demand* and largely self-sustaining growth. The current evidence shows strong progress but mostly in **targeted domains** (military, industrial, research) rather than everyday life. In short, the technology is transitioning from early adopter phase to wider adoption, but hasn’t fully broken into a mass-market or multi-industry mainstream usage with “rising demand” across the board. Key missing pieces to justify level 7 include: ubiquitous safety certification frameworks (allowing routine unsupervised use in shared spaces), larger scale manufacturing driving down costs (units are still as expensive as specialized equipment), and longer track records of reliability that would spur *unhesitating* customer demand.

**C) Sub-component breakdown:**

- **Aerial autonomous drones:** *Maturity*  $\approx$  6. Small and mid-size autonomous drones have active competition and deployment. Evidence: utility and industrial inspections using fleets of drones (Percepto/FPL)[3], government research investing in multi-drone swarms[5], and numerous vendors (DJI, Skydio, etc.) selling autonomous navigation drones. Drones benefit from decades of R&D in autopilots and now AI, so many tasks (mapping, surveillance) can be done with minimal human input.

- **Ground robots (UGVs):** *Maturity*  $\approx$  5–6. Mobile robots that navigate human environments autonomously are emerging from pilot stage. The data of 1000+ quadrupeds deployed[13] and new models like ANYmal X selling hundreds of units[12] show a commercial foothold. However, ground robots face more regulatory/social hurdles (e.g. public perception, dealing with people and obstacles in cluttered spaces) – their use is currently mostly in controlled industrial sites or pilot programs (factories, warehouses, military exercises).

- **Underwater robots (AUVs):** *Maturity*  $\approx$  4–5. Technically, some AUVs are very advanced (multi-day endurance, deep-ocean autonomy proven in trials[8]). Agencies and companies

are now procuring these (e.g. Navy's Orca in 2023[9], Kongsberg's deliveries in 2024), which is a leap from purely experimental models. Still, the number in operation is limited, and each unit is often bespoke or low-volume production. The underwater sector is likely a step behind aerial drones in commercialization pace, due to higher costs and narrower use-cases (scientific surveying, naval missions).

Taking an **average** of these sub-scores (driven by the fact that they address different environments and markets), the bundle as a whole sits around **level 6**. In essence, *the enabling technologies are all demonstrated and one by one entering real use, with active players pushing them toward scalable products*. The score of 6 reflects that **multiple autonomous robot types are already being delivered to paying users and scaled up**, though not yet a completely mature, ubiquitous commodity. The evidence above shows recent rapid progress, and with continued R&D and investment (and some regulatory evolution), this ART is on the cusp of broad impact within the next decade.

## ART 05.034 Supportive Infrastructure for Autonomy

### 46. ART extraction

**A) Primary capability:** “*Supportive Infrastructure for Autonomy*” aims to turn physical environments into structured, robot-friendly spaces. The core capability is embedding an **intentional infrastructural layer** in buildings, vehicles, and public areas that actively assists autonomous robots. This makes environments **legible, predictable, and serviceable** for fleets of mobile robots and robotic manipulators, rather than forcing each robot to handle arbitrary, unstructured settings. It enables high-density, **coordinated multi-robot operations** that are safer and more reliable by offloading perception, navigation, and coordination tasks to the environment itself.

### **B) Key sub-components/variants:**

- **Robot-readable markers & surfaces:** Physical tags or standardized markings (e.g. visual fiducials, QR codes, reflective strips) embedded in floors, walls, or objects to convey position or identity information to robots, simplifying perception and navigation.
- **High-precision localization fields:** Installed infrastructure (like ultra-wideband beacons, Wi-Fi/UWB anchor grids, or vision-based reference points) that provides **centimeter-level positioning** for robots indoors where GPS is unavailable[1]. This allows robots to localize quickly and accurately without expensive onboard sensors.
- **Standardized docking & payload stations:** **Universal charging docks, battery swap stations, and load transfer points** built into the environment, enabling any compliant robot to autonomously recharge or exchange payloads. These are designed for interoperability (common connectors or wireless charging) so different vendors' robots can use the same infrastructure.
- **“Coordination posts” & traffic control units:** Distributed computing nodes or cloud services that manage multi-robot traffic and safety. They enforce **shared “rules of the road”** (right-of-way, speed limits, collision avoidance) for heterogeneous robots in the area, often by

monitoring positions and orchestrating movements via V2X (vehicle-to-everything) communications. Robots can request access to certain lanes or zones through these coordination points, which negotiate priorities and prevent deadlocks.

- **Digital interfaces & APIs:** A unified **environment API** through which robots query the infrastructure for map data, reserve corridors or elevators, get dynamic updates (e.g. construction zones or human worker presence), and obey environment-specific constraints. This requires common protocols/standards so robots from different manufacturers can all communicate with the infrastructure.

- **Human interaction & oversight tools:** Clear **physical cues** (lights, signals, designated robot lanes) that let people intuitively understand robot operating zones and statuses. **Call buttons or request stations** for humans to summon or dispatch robots. Central **fleet operations dashboards** for human supervisors to monitor robot activities in real time, inspect their status, and intervene or override if needed – ensuring all autonomous behavior is transparent and interruptible by people.

### C) Maturity indicators to seek:

- *Field demonstrations or pilot deployments* where environments have been retrofitted with robot-support infrastructure (e.g. warehouses, factories, hospitals, or campuses instrumented with markers, beacons, central controllers) and shown measurable improvements in robot efficiency or safety.

- *Interoperability standards or consortia* – evidence of industry-wide efforts (standards bodies, working groups) defining common interfaces for robot/environment communication, docking hardware, or fleet management protocols (for example, a standard for sharing a charging station or traffic data between different robots).

- *Prototype to product transition:* Existence of commercial **products or platforms** offering infrastructure-based solutions – e.g. companies selling multi-robot management systems, “autonomy through infrastructure” sensor networks, or standardized docking stations. Competing well-funded startups or consortium projects would indicate momentum toward commercialization.

- *Performance metrics beyond classical autonomy:* Data showing that with supportive infrastructure, robots achieve **higher reliability or lower cost** than standalone autonomy – e.g. simpler robots navigating with infrastructure assistance, precise indoor localization (few cm error) achieved via installed beacons, or denser robot traffic with no collisions under a coordination system.

- *Investment and scaling signals:* Reports of major facility upgrades for robot infrastructure (e.g. a factory spending capital on installing sensors or markers), or multiple deployments in “high-utilization zones” (like busy warehouses, airports, or hospitals) indicating that the value justifies the cost in certain scenarios. Funding rounds or partnerships (robot makers teaming with infrastructure providers, large end-users trialing the tech) would also reflect maturity.

#### 47. Evidence (10–20 recent, reliable sources):

48. **“Infrastructure to support robots: a practical, scalable model for comparative evaluation of design choices”** – G. McFassel, D. Shell (Texas A&M University); *IROS 2023, peer-reviewed conference paper; 10/2023. Link: [PDF][2]. Researchers formalize the notion that structured environments make robots more effective. They introduce a quantitative model (MDP-based) to evaluate adding infrastructure (markers, sensors, etc.) around robots. The model computes how many robots are needed for an infrastructure investment to pay off, when installation costs are recouped through performance gains, and how robot behaviors improve with such*

environmental modifications[3]. This provides a theoretical foundation to justify investing in robot-friendly infrastructure and helps identify break-even points, reinforcing the plausibility that such infrastructure can yield net economic and performance benefits.

49. **“An Experimental Evaluation of Indoor Localization in Autonomous Mobile Robots”** – O. Dagdeviren et al.; *Sensors (MDPI)*, peer-reviewed; 04/2025. **Link:**[4]. Compares indoor positioning technologies for mobile robots and finds Ultra-Wideband (UWB) outperforms Wi-Fi and BLE by a wide margin. With just 4 UWB anchors covering a 431 m<sup>2</sup> area, the system achieved <13.1 cm error (static) and ~28–30 cm error for moving robots[1] – an 88% accuracy improvement over Bluetooth and 93% over Wi-Fi. The study notes that UWB’s high precision, few anchors needed, and dropping hardware costs make it a prime candidate for “dominating technology in indoor tracking systems in the near future”[5]. This validates the feasibility of the “high-density localization fields” aspect of the ART: robust, infrastructure-based localization is technically mature and can reliably guide robots with centimeter accuracy indoors.
50. **“Positional inaccuracy investigation and innovative connection solution for robotic construction of load carrying structures”** – C.P. Chea, Y. Bai, Y. Fang; *Journal of Infrastructure Intelligence and Resilience*, peer-reviewed; 06/2025. **Link:**[6]. Describes a multi-robot construction experiment where two mobile robots and robotic arms collaboratively assembled a structure. The team embedded AprilTag fiducial markers in the environment as a positioning system to align the mobile robots and target components during assembly[6]. By using these robot-readable markers with an RGB-D camera, they quantified the positioning accuracy and even developed a magnetic self-alignment mechanism to counter minor errors. The successful automated assembly demo shows that adding simple visual infrastructure (tags) can significantly aid robot navigation/precision in complex tasks, underscoring the ART’s claim that “autonomy-native” modifications (like markers) make previously infeasible automation tasks viable by reducing robots’ cognitive burden.
51. **BMW Group’s Dingolfing Factory Pilot – Autonomy through Infrastructure** – BMW Group with Seoul Robotics & Embotech; BMW Press Release; 07/2022. **Link:**[7]. BMW deployed a pilot system where newly produced cars navigate autonomously through a factory area guided entirely by infrastructure sensors and a central controller (no onboard LIDAR/vision in the vehicles). The route (170 m) is equipped with cameras and LiDARs running Seoul Robotics’ perception software for vehicle localization and environment recognition, plus Embotech’s motion planning software to steer/brake the vehicles via V2X commands[7]. This “Automated Factory Driving” project (AFW) lets cars drive themselves from assembly to dispatch, using fixed infrastructure as the “eyes and brain.” It was slated to run through 2023 and then scale to more production lines[8]. Why it matters: This is a real-world proof-of-concept of the ART – a major OEM installed a shared infrastructure layer to automate vehicle movement\*, achieving Level-5 autonomy on private grounds without expensive vehicle sensors. It demonstrates both plausibility (technology works: the environment can safely choreograph multiple driverless vehicles) and progress toward maturity (a leading carmaker invested >€300 million in factory upgrades including this system).
52. **“VDA 5050 Explained – An Overview of the Evolving AGV Communication Standard”** – BlueBotics (Switzerland) tech blog; 08/2024. **Link:**[9][10]. Industry associations in Germany (VDA & VDMA) have developed VDA 5050, a standard interface to allow heterogeneous AGVs/AMRs and a central fleet software to communicate regardless of manufacturer. Version 2.0 was published in Jan 2022[9], expanding the standard to support sending actions (e.g. “slow down”) and for robots to share a detailed capability “fact sheet.” The blog notes that VDA 5050 is still in pilot/testing phase – it’s a “proposed” standard expected to evolve over 2–5 years, and currently no robot is fully compliant since the spec isn’t final[10]. Some early adopter projects have integrated mixed fleets via VDA 5050, but these required significant

custom coding for each new robot type and will need rework once the standard finalizes[10]. Relevance: This shows active efforts to achieve widely accepted interoperability standards – a key ART enabler – but also highlights that in 2022–2024 the process is ongoing. It indicates multiple vendors and end-users (e.g. BMW, which is cited as using VDA 5050) are collaborating to make shared infrastructure (like fleet managers, shared chargers, traffic control) a reality, even if full plug-and-play interoperability is a couple years away.

53. **“Multi-robot orchestration software focused on logistics improvement launched”** – Plant Engineering magazine; 03/2023. Link:[11][12]. Reports on the U.S. launch of CoEvolution’s AI-powered multi-robot orchestration platform at ProMat 2023. This software can control different brands and types of robots simultaneously, coordinating them “as a homogeneous fleet”[11]. By unifying control, it allows robots that traditionally operate in separate zones to work together in the same space, greatly improving space utilization and efficiency in warehouses[12]. The platform provides centralized traffic management and task orchestration across AMRs that handle various functions (forklifts, shelf carriers, etc.). CoEvolution cited that demand for multi-fleet orchestration is skyrocketing (projected 138% CAGR globally through 2027), as large warehouses seek to optimize mixed robot operations[13]. Significance: This is evidence of a commercial solution directly addressing the “coordination layer” of the ART. Multiple vendors (CoEvolution, and others like InOrbit, see below) are now competing in this space, indicating the transition from concept to market. The product’s value proposition – higher density robot traffic without chaos – aligns exactly with the ART’s goal of “dense, choreographed machine activity” enabled by shared rules and scheduling.
54. **“Scalable and heterogeneous mobile robot fleet-based task automation in crowded hospital environments – a field test”** – R. Valner et al. (Univ. of Tartu, Estonia); *Frontiers in Robotics & AI*, peer-reviewed; 08/2022. Link:[14]. Documents a real-world deployment of an open-source Robotics Middleware Framework (RMF) to coordinate a mixed fleet of service robots in a busy hospital. In Tartu University Hospital, the team deployed multiple mobile robots to transport lab samples through narrow, human-crowded corridors. The system used RMF as the interoperability and scheduling layer for different robots and IoT devices, handling task distribution and navigation in a human-aware manner[14]. They report lessons learned from this heterogeneous fleet automation and provide source code. Notably, RMF (developed by Open Robotics) is described as “highly capable... yet to reach full maturity,” meaning some integration challenges had to be overcome[14]. Why important: This is a field validation of the ART concept in a complex, unstructured environment (a hospital). It shows that with a coordination framework and some infrastructure (the robots share maps and schedules via RMF, and integrate with building elevators/doors), autonomous delivery can work even around crowds. It also underscores current limitations – continuous calibration/safety adjustments were needed, echoing the ART’s note that such infrastructure requires ongoing assurance as layouts and usage change.
55. **Human Oversight & Interoperability Platforms – (InOrbit, Meili Robots)** – Singh et al., FORMIGA project; *Frontiers in Robotics & AI*, 2025. Link:[15]. A 2025 robotics article reviews state-of-the-art fleet management systems and notes that commercial “RobOps” platforms now exist to supervise robot fleets with human-in-the-loop control. For example, InOrbit provides cloud-based dashboards for real-time fleet monitoring, incident alerts, and intervention, and includes tools to handle autonomy exceptions (like localization failures) remotely[15]. Likewise, Meili Robots offers an interoperability platform with features like shared maps, traffic control, and support for standard protocols (HTTP/MQTT, etc.) to link diverse robots[15]. These systems emphasize scalability (managing dozens to thousands of robots) and transparency, allowing operators to visualize and optimize fleet behavior. This evidences the “human interface and oversight” part of the ART: robust supervisory control products are

*emerging to make machine behavior inspectable and interruptible by humans, which is crucial for safety and trust. It also shows focus on interoperability – multiple robot types can be integrated via such platforms, aligning with the need for environment-level coordination across vendors.*

56. **“Autonomous Multirotor UAV Docking and Charging: A Comprehensive Review”** – I. Petrovic et al.; *Symmetry* (MDPI), peer-reviewed; 11/2025. **Link:**[\[16\]](#). Although focused on drones, this review highlights a broader infrastructure issue relevant to all robots: the lack of standardized docking/charging systems. It notes that current autonomous docking solutions are fragmented, and “a standardized system needs to be implemented to provide industry standards for docking systems in accordance with charging protocols and safety regulations.”[\[16\]](#) In other words, researchers call for uniform design of charging contacts, battery swap interfaces, and safety interlocks so any robot can use any compliant dock. Relevance: The ART’s vision includes standardized energy and payload transfer nodes; this source affirms that as of 2025, the community sees standardization as an unmet need (docking is still mostly proprietary). It underscores a current maturity gap: while one-off solutions exist (various vendors have made auto-chargers), an agreed standard would greatly accelerate deployment of such infrastructure at scale.

#### 57. Maturity score (1–7) and reasoning

**Overall Maturity Score: 5 (out of 7)** – The technology bundle “Supportive Infrastructure for Autonomy” is at **Level 5: early commercial prototypes with active industry competition, but not yet broadly adopted or scaled.**

**A) Why it’s not lower:** Multiple lines of evidence show we’ve moved past pure theory (Levels 1–2) and lab demos (Level 3). There are **functioning prototypes and pilots in real operational environments**, which is characteristic of Level 4 and above. For example, BMW’s 2022 pilot in a factory used infrastructure sensors to autonomously maneuver real vehicles[\[7\]](#) – a significant Proof-of-Concept in an industrial setting. Similarly, the Tartu hospital trial (2022) successfully integrated a heterogeneous robot fleet using a centralized framework[\[14\]](#), and startups like CoEvolution have demonstrated orchestration of mixed robot fleets in warehouses[\[12\]](#). These achievements show that the key blockers (like multi-robot traffic control and precise indoor positioning) **have been solved in prototype form**. Importantly, we also see **active funding and industry collaboration**: well-capitalized companies and consortia are working on standards (MassRobotics AMR group, VDA 5050 in 2022[\[9\]](#)) and launching products (e.g. multi-fleet management software in 2023[\[11\]](#)), indicating a commercial drive that goes beyond isolated experiments. This rules out Level 4; the field is no longer at a single proof-of-concept – it’s now about **refining and converging prototypes for broader deployment**, which aligns with Level 5.

**B) Why it’s not higher:** Despite progress, the **infrastructure is not yet widely deployed or standardized** – keeping it below Levels 6–7 (which require competing products delivered at scale and rising customer demand). The evidence highlights ongoing challenges that must be resolved before mass adoption: for instance, the need for **widely accepted standards** is still a bottleneck. The VDA 5050 case shows that while a version exists, full interoperability “promise is still out of reach” in 2024 without custom engineering[\[10\]](#). Likewise, the MDPI review (2025) explicitly calls out the absence of standard docking protocols[\[16\]](#) – meaning each new environment retrofit today often requires bespoke solutions, limiting scalability. There have been only *selective deployments* in high-utilization settings (one car factory pilot, a few warehouses/hospitals in trials), and those tend to be **costly, custom integrations**

rather than off-the-shelf rollouts. No evidence yet shows broad customer adoption or large production orders of “autonomy infrastructure” as a product – most projects are still pilots or early-stage deployments, and many existing robot installations still rely on robots’ onboard autonomy rather than instrumented environments. In short, the concept is proven viable (robots *can* benefit enormously from infrastructure support), but the ecosystem is in an **early commercialization phase**: multiple players are racing to define standards and offer solutions, and end-users are just beginning to test these in live operations. This fits Level 5, where well-funded actors are converging on production prototypes but market penetration remains limited.

**C) Sub-component breakdown:** *The ART comprises a bundle of technologies with different maturity levels, so we assessed each and averaged:*

- **Precision localization infrastructure: Level 6.** Technologies like UWB beacons and fiducial markers are quite mature – they’re already used in industry for indoor robot navigation (e.g. UWB-based RTLS is being shipped with ~10 cm accuracy[11]). Many warehouses use floor tags or reflectors for AGV guidance. The capability to localize robots via environment aids is essentially a solved problem technically and is in commercial use, although often in siloed, vendor-specific ways.
- **Robot coordination & fleet management systems: Level 5.** We see multiple startups and platforms (InOrbit, Meili, CoEvolution, Open-RMF) providing the “traffic control and scheduling” layer[11][15]. This segment has active competition and initial customers (especially in warehousing and logistics), and standards like VDA 5050 are being collaboratively developed[9]. However, the market is still shaking out – interoperability between systems is limited and many deployments are in pilot phase. The presence of at least **half a dozen players** and rapid growth forecasts for multi-robot orchestration show that the race is on (a hallmark of Level 5), even if a dominant design isn’t settled yet.
- **Standardized docking & physical infrastructure hardware: Level 3–4.** While automatic charging stations and tool-changing docks exist, there is **no widely adopted standard** (confirmed by calls for standardization in 2025[16]). Each vendor has its own approach (for example, one AMR might use QR codes for docking alignment, another uses Lidar), and retrofitting a facility with universal docking nodes is still mostly experimental. Some prototypes demonstrate >90% autonomous docking success in labs[17], but cross-compatibility and cost-effectiveness remain issues. This sub-component lags others; it’s around proof-of-concept to early prototype stage.
- **Human oversight interfaces: Level 5.** Fleet operations dashboards and robot supervision tools are available (InOrbit’s platform, for instance, is a product used by companies to manage robotics deployments[15]). The integration of humans into the loop (through control centers, alert systems, or “call buttons” in facilities) is being built into most commercial fleet software. It’s not fully standardized, but essentially every serious multi-robot solution now considers human interaction, indicating this aspect is keeping pace with the coordination systems above (around Level 5).

Given these differences, the **overall functionality is only as strong as its weakest links** – a fully “autonomy-native” environment requires all components (localization, coordination, docking, standards, HMI) to work together. Right now, some pieces (like localization) are ready to deploy, while others (like universal docking and true multi-vendor plug-and-play) are

still emerging. Therefore, we aggregate to **Level 5** as a balanced score. This reflects that *in limited high-value domains the infrastructure is moving into deployment*, but a comprehensive, standardized rollout across industries is a few steps away. Achieving Level 6/7 will require ironing out standards and reducing retrofit costs so that such supportive infrastructure can be installed broadly rather than only in bespoke, high-cost projects – a transition we expect to see as current pilots prove value and drive wider adoption.

## ART 05.035 Optical/Microwave Power Beaming for Persistent Robotics

### 58. ART extraction

59. *Primary capability*: Enabling robots and remote devices to receive electric power via directed energy beams (laser or microwave), freeing them from bulky onboard batteries or frequent manual refueling. This promises **persistent operation over long durations** by delivering power wirelessly over line-of-sight distances, much like an “energy Wi-Fi” that can keep drones aloft or sensors active continuously.

60. *Key sub-components/variants*:

- **Optical (laser) power beaming** – high-intensity laser transmitters paired with photovoltaic receivers (specialized solar cells) to convert light to electricity. Offers tight beam focus and small receiver size, but performance can degrade in fog/rain and requires eye-safety measures.
- **Microwave/millimeter-wave power beaming** – phased-array microwave transmitters and rectenna receivers (antenna + rectifier) to convert RF to DC. Better penetration through weather and potentially safer power densities, but needs larger antennas for long range and faces spectrum regulation[1][2].
- **Beam tracking and relay networks** – gimbal or phased-array beam steering systems, plus sensors and software for active tracking of moving targets (drones, vehicles) to maintain alignment. May include airborne relay platforms to extend range beyond line-of-sight[3][4].
- **Safety & control subsystems** – fail-safes that cut off power if an object enters the beam, and power-density limits to avoid harming people, wildlife, or other equipment[5][6]. Also, software interfaces to allocate and schedule power delivery across multiple receivers (analogous to communication network management).

61. *Maturity indicators (evidence)*: We would expect **experimental prototypes and field trials** that demonstrate powering of real robots (e.g. keeping a drone flying for hours via beam). Key evidence includes: high-power transmissions over significant distances with efficient conversion; **continuous operation tests** (not just momentary lab experiments); integration of tracking and safety in realistic environments; **multiple organizations investing** (defense agencies, space agencies, companies) and moving from lab demos to deployable systems. Indicators of maturity would be **working proof-of-concept systems** meeting mission requirements (power level, range, safety)[7][8], and efforts to scale up (e.g. plans for operational pilots, commercial products, or standardization efforts).

62. **Evidence (10–20 recent, reliable sources)**

63. **DARPA long-distance laser power beaming record – May 2025 (U.S. DoD) – DARPA News Release**. DARPA’s POWER program set a new benchmark by delivering **>800 W of optical power over 8.6 km** in tests at White Sands, using a novel receiver with dozens of photovoltaic cells and a parabolic concentrator[9][10]. Over 1 MJ of energy was beamed in total, **shattering previous records** (previously 230 W at 1.7 km)[11]. This demonstrated unprecedented range and power, proving feasibility for powering remote sites or drones from the ground. It also validated >20% end-to-end efficiency

at shorter range with the new receiver design[12], showing that practical conversion efficiencies are achievable. This is a major plausibility milestone, indicating that high-intensity laser links can be maintained over tactical distances.

64. **NRL “SCOPE-M” microwave beaming demo (1.6 kW over 1 km) – Apr 2022 (U.S. Navy)** – *Navy Research Lab Press Release*. A Naval Research Laboratory team achieved **1.6 kW wireless power transfer across 1 km** using a 10 GHz microwave beam, the most significant power beaming demo in nearly 50 years[13][14]. Conducted at an Army range in Maryland, it exceeded the 1-kW target by 60%. Importantly, it stayed within internationally defined safety limits – the power density was low enough to be intrinsically safe for birds and people, without needing an interlock shutdown[5][6]. NRL also demonstrated the system at a second site (MIT), showing higher average power delivery over time[15]. NRL’s Paul Jaffe stated this work is **“very close to demonstrating a system we can deploy”**, highlighting that the remaining issues are being solved to move from experiment to usable field system[16]. This validates engineering feasibility for microwave beaming (which works in all weather) and shows military interest in near-term deployment to power remote bases or equipment.
65. **NTT/Mitsubishi 1-kW laser wireless power trial – Nov 2025 (Japan industry)** – *Technical news (Science Japan)*. In a public outdoor experiment, Nippon Telegraph & Telephone (NTT) and Mitsubishi Heavy Industries beamed a **1.035 kW laser over 1 km** to a silicon photovoltaic receiver, yielding ~152 W DC output (15% efficiency)[17][18]. They maintained the link for **30 minutes continuously**[18] under strong atmospheric turbulence (near-ground horizontal path), using beam-shaping optics and a beam homogenizer to counter intensity distortions[19][20]. This is the world’s highest reported efficiency for laser power transfer with a silicon PV under turbulent conditions[21]. It shows that **commercial players are tackling real-world issues** (beam spreading, atmospheric interference) and achieving stable power delivery over substantial distances. The success suggests viability for powering “remote locations where cables are hard to use,” with envisioned applications from isolated islands to drones and even satellites[22].
66. **Caltech Space Solar Power Demonstrator (MAPLE) – June 2023 (U.S. academia)** – *Caltech News*. Caltech’s Space Solar Power Project launched a prototype to orbit in Jan 2023, which **wirelessly transmitted power in space and to Earth** for the first time[23][24]. The MAPLE experiment consisted of a flexible array of microwave transmitters with custom chips. In March 2023 it lit up onboard LEDs via wireless transfer in free space, and in May 2023 it **beamed a detectable microwave signal down to a Caltech ground station**[25][26]. Though only a very small amount of power was received on Earth, this proves that a lightweight phased array can survive launch and operate in space as intended. It marks a crucial plausibility step for space-to-ground power beaming, validating that key components (flexible arrays, beam steering) work in the harsh space environment[24][27]. This boosts confidence in the underlying science and informs next designs, even as terrestrial applications are pursued in parallel.
67. **First power beaming from a moving aircraft – Nov 2025 (Overview Energy, U.S.)** – *IEEE Spectrum (reporting on startup demo)*. Startup Overview Energy demonstrated optical power beaming from a **moving airplane to ground receivers** – a Cessna aircraft at 5,000 m beamed near-infrared power while in flight[28][29]. Only a small

amount of power was transmitted (a “sprinkling”), but it used the same hardware the company plans for space solar satellites[30]. This is the **first-ever airborne moving-platform power beaming test**, showing that pointing and tracking can work in a real flight with turbulence and crosswinds. It validates a key capability needed for dynamic “power-at-a-distance” networks. Notably, former DARPA program manager Paul Jaffe joined the company, citing that the approach “gets around a lot of the showstoppers” and **appears technically viable for scaling up**[31][32]. This indicates growing expert confidence and the involvement of experienced talent to transition the tech beyond lab.

68. **Airbus “Power Beaming” lab demonstration – Sept 2022 (EU industry) – Airbus Newsroom (Innovation web story).** Airbus’ X-Works lab built a pilot system illustrating space solar power: in a demo for policymakers, they used **microwave beaming over 36 m** indoors to transmit energy from a “Space” transmitter to an “Earth” receiver, which in turn **produced green hydrogen and powered a model city**[33]. The setup used a ~5.8 GHz beam (with ~1.9 m antennas per reports) and represented a satellite sending power to ground[34]. While small-scale, it showcased end-to-end functionality (conversion of beam power to useful work like hydrogen generation) and was **successful in impressing stakeholders**[33]. Airbus estimates that by the early 2030s, operational prototypes could be in use, following a stepped approach from ground tests to aerial, then orbital systems[35]. They emphasize that at scale, the economics could rival large terrestrial energy projects, and that power-beaming could be a “game changer” for aircraft and energy distribution[36][37]. This demonstrates serious interest in Europe and the convergence of aerospace and energy sectors to push the technology.
69. **Emrod and ESA long-range WPT demonstration – Sept 2022 (NZ/EU startup collaboration) – Energy Global trade article.** New Zealand startup Emrod, with funding from ESA and Airbus, conducted **Europe’s first long-range wireless power demo for space solar applications**[38][34]. At Airbus’s site in Munich, Emrod’s system beamed power **over 36 m at 5.8 GHz** using a phased array ~1.92 m in size on both transmitter and receiver[34]. This achieved the conversion efficiency and alignment needed to convince ESA to propose a program (SOLARIS) to pursue space-based solar power[38]. ESA’s tech director noted this as a showcase of WPT as an emerging technology to solve sustainability challenges[38]. Emrod’s CEO announced they are now planning a larger terrestrial use-case demo and preparing for in-orbit tests[39]. The event underscores that **startups and agencies are actively de-risking the tech**, and that moderate-range microwave beaming is already functioning in a prototypical form.
70. **PowerLight “Infinite Flight” laser charging system – Dec 2025 (U.S. company) – Company Press Release.** PowerLight Technologies (formerly LaserMotive) unveiled a fully integrated **ground-to-air laser power beaming system** for drones, developed under a U.S. CENTCOM-sponsored program[40][41]. The system couples an autonomous high-power laser transmitter (with precision optical tracking and multi-layer safety interlocks) and a lightweight onboard receiver that converts the beam to DC to recharge the UAV’s battery in flight[42][43]. In testing, it has delivered “kilowatt-class power over kilometers” and successfully tracked moving UAS targets in real time[44][45]. By late 2025 it moved from component tests to integrated system tests, and **full flight demonstrations are scheduled for early 2026** on an ultra-long-

endurance drone platform[46]. This marks a true **proof-of-concept prototype aimed at operational use**, with a specific customer (DoD) in mind. The presence of safety-certified features and plans for imminent flight trials indicate the technology is transitioning out of the lab.

71. **Army STTR solicitation for powered UAVs – Apr 2023 (U.S. government) – U.S. Army SBIR Topic A23B-T023.** The U.S. Army issued a call for small-business R&D to develop a **power-beaming system for Group 1 drones** (under ~20 lb)[47][8]. The objective is a prototype that can deliver >100 W continuously to a drone at 500 m or more, ideally enabling indefinite flight (>200 W for unlimited endurance)[8]. The topic notes prior demos (e.g. a laser link to a UAV in a wind tunnel) and the need to progress to a more “relevant outdoors” demonstration with the drone in flight[48]. It highlights technical challenges: keeping a high-power beam locked on a moving target despite turbulence, ensuring eye safety, and managing the added weight/heat on the drone[49]. This solicitation is evidence that **military end-users see enough promise to invest in accelerating the technology**. It defines concrete performance targets (100–200 W at multi-hundred-meter range, eye-safe operation) that align with real mission requirements (doubling or eliminating the need for battery swaps)[8]. The funded effort will push lab successes toward field-capable prototypes, indicating the field is moving beyond academia into applied engineering development.

## 72. Maturity score (1–7) and reasoning

### Proposed Maturity Score: 4 (Proof-of-Concept demonstrated)

**A) Why not lower:** The core feasibility of optical/microwave power beaming is **well past theoretical and lab validation (Levels 1–2)**. In the last few years we’ve seen **multiple full-system demonstrations (Level 3)** that solved key hurdles: e.g., NRL’s microwave demo showed kW-level delivery over 1 km with safety and efficiency managed[13][5]; DARPA’s laser test achieved unprecedented range/power, breaking misconceptions about distance limits[9][50]. Importantly, we now have at least one **integrated prototype at or near operational conditions (Level 4)** – the PowerLight laser-UAV system with autonomous tracking and safety, slated for flight testing of “infinite” endurance in 2026[44][46]. That system combines all necessary pieces (high-power source, beam steering, airborne receiver, energy storage) and is backed by end-user interest, indicating it meets many functional requirements for real deployment. Likewise, Airbus and Emrod’s 2022 demos, though small scale, integrated generation, transmission, and usage (even making hydrogen), underscoring that the concept works end-to-end[33]. These achievements rule out Levels 1–3: the technology is beyond theory and isolated lab experiments – it **exists as functional prototypes tackling real-world conditions** (atmospheric turbulence, mobile targets, etc.).

**B) Why not higher:** The leap to Level 5 or above would require evidence of **multiple competing commercial products or near-products** and rapid scaling toward market. We are not quite there yet. While well-funded players are involved (DARPA, ESA, Airbus, CENTCOM, etc.), and startups like PowerLight, Emrod, and Overview are in the mix, we don’t yet see **products being sold or widely deployed (Levels 6–7)**. There is not yet a **fleet of robots powered by these systems in continuous use**, only one-off demos and pilot projects. No public evidence shows multi-company competition delivering units to customers at scale – most efforts are still government-sponsored trials or prototypes. To reach Level 5, for example, we’d expect several companies racing to finalize production-ready systems or clear plans for commercial launch. Instead, we see one company (PowerLight) just entering flight demo phase[46] and another (Emrod) preparing a terrestrial pilot[39]. **No off-the-shelf power-beaming infrastructure exists yet**; regulatory frameworks

(especially for high-power lasers/microwaves) are still in development. In short, the concept has been proven viable (hence Level 4), but it **has not reached commercial rollout**. Further evidence needed for the next level would include things like year-long field deployments powering real autonomous platforms, multiple vendors with turnkey systems, or significant private investment scaling manufacturing – none of which has been fully realized as of now.

**C) Sub-component considerations:** This ART comprises two main technical variants – **laser-based and microwave-based power beaming**. Both aim at similar functionality (untethered power delivery) and are at comparable maturity: each has seen successful prototypes but no wide adoption yet. Laser systems (optical) have achieved higher beam precision and have a clear path for drone applications (e.g., PowerLight’s kW-class laser charger nearing field test[51][46]). Microwave systems have demonstrated larger distances and weather-robust operation (e.g., NRL’s 1-km/1.6 kW and the Airbus/Emrod demo)[13][34], which is promising for infrastructure-scale use. **Neither variant is fully mature alone**, but together they reinforce the overall concept’s viability. Since their **functionality overlaps (each can service similar use-cases) and progress is parallel**, we treat the bundle’s maturity as a whole. Both sub-techs are roughly in the PoC/prototype stage, so averaging their maturity still yields  $\approx 4$ . We therefore assign **Level 4** as the composite score – **working prototypes exist proving the concept’s value, but commercial exploitation is still in its infancy**. The score reflects that the fundamental technology is demonstrated and on the cusp of practical deployment, while acknowledging that the transition to widespread, competitive products is the next step still to come.

## ART 05.036 Gecko-Inspired Dry-Adhesion Mobility & Manipulation

### 1. ART extraction

- **Primary capability:** Enable strong yet residue-free adhesion on surfaces (even smooth or inverted) using micro-/nano-structured “gecko” pads that grip via van der Waals forces rather than suction or glue. This allows robots to **attach, climb, or grip objects** securely and **quickly release** by switching adhesion off, even in vacuum or low-pressure environments where conventional suction fails.

- **Key sub-components/variants:** Advanced **dry adhesive materials** (arrays of micro/nanofibers or wedges inspired by gecko setae) providing high shear and normal adhesion; **mechanical switching mechanisms** (controlled preload, shear or angle orientation, stiffness-tunable backing) to turn adhesion on/off; **embedded sensors** (e.g. capacitive or piezo sensors in the adhesive backing) to detect contact area and adhesion force in real time; **actuated mounts** (robotic fingers, tiles or track modules) that apply and peel the adhesive under software control; and **manufacturing techniques** (microfabrication, 3D printing, roll-to-roll processes) to produce large-area, durable adhesive pads. Application variants include gecko-like **robotic grippers** for smooth or delicate objects, **wall-climbing robots** or perching drones for vertical/overhead surfaces, and adhesive anchoring devices for space or industrial use.

- **Maturity indicators:** Evidence of **lab prototypes solving prior blockers** (e.g. rapid

switching adhesion, self-cleaning of dust, sensing integration), **field demonstrations** (robots using gecko adhesives in real environments like the International Space Station or factories), and **early commercial adoption**. Indicators include functional **proof-of-concept devices** meeting practical load and cycle-life requirements; **industry products or pilot programs** (e.g. an adhesive gripper sold for automation tasks); ability to **manufacture** adhesive pads in quantity with consistent performance; **multi-cycle durability** (tens of thousands of attach-detach cycles without failure); and **investment or partnerships** (multiple companies, including major materials or robotics firms, investing in or bringing products to market, signaling competition and scaling efforts).

## 2. Evidence (10–20 recent, reliable sources)

73. **Gecko-inspired self-sensing adhesive for intelligent adhesion – S. Li et al. (North Univ. of China & Xi'an JITU)** – *Chemical Engineering Journal*, 11/2025 (peer-reviewed)[1][2].  
*Researchers demonstrate a dry adhesive pad with an integrated flexible capacitive sensor backing, mimicking gecko skin's tactile feedback. The system can measure adhesion force in real time and achieved reliable sticking even on angled surfaces by using a compliant backing layer, addressing the lack of feedback and off-angle performance in earlier gecko adhesives.*
74. **Gecko Toe Pad-Inspired Robotic Gripper with Rapidly and Precisely Tunable Adhesion – S. Li et al.** – *Research (AAAS Open Science Journal)*, accepted 04/2025 (peer-reviewed)[3][4].  
*Presents a robotic gripper that uses gecko-inspired pads and a self-peeling mechanism to switch adhesion on/off in under 0.5 s, allowing it to pick up and release objects like glass sheets, silicon wafers, and flexible films. The gripper can modulate adhesion strength from 0 up to ~82.8 kPa by adjusting pad peeling angle, enabling fast handling of thin, fragile or heavy objects without residue. This indicates a major step in precision industrial grippers using dry adhesion.*
75. **Gecko-Inspired Controllable Adhesive: Structure, Fabrication, and Application – J. Liu et al.** – *Sensors & Actuators (Review)*, 03/2024 (peer-reviewed)[5][6]. *Comprehensive review of gecko-inspired adhesion technologies, covering designs like shape-memory polymer adhesives, magnetically switchable microstructures, and tunable backings, as well as fabrication methods (photolithography, 3D printing, etc.). It notes that while lab prototypes show high adhesive strength, scaling up production to large-area adhesives efficiently remains a challenge, and integrating all the gecko-inspired mechanisms into one product is a future goal. This underscores both the breadth of R&D in the field and the remaining hurdles in manufacturing and integration[6].*
76. **Testing Gecko-Inspired Adhesives with Astrobee Aboard the ISS – T. G. Chen et al. (Stanford/NASA Ames)** – *IEEE Robotics & Automation Letters*, 2022 (peer-reviewed)[7].  
*Reports the first on-orbit tests of a gecko-adhesive gripper on NASA's Astrobee free-flying robot inside the International Space Station. In early 2021, the adhesive gripper reliably perched on surfaces in microgravity, providing ~3.15 N of holding force for the robot[7]. The gecko materials performed as expected even after long storage in space, demonstrating functionality in vacuum/low-pressure and raising the technology's TRL for space applications. This validates the plausibility of dry adhesives for anchoring robots in environments where suction or magnets don't work.*
77. **OnRobot Gecko Gripper (SP Series)** – *OnRobot A/S (Denmark) product technical info*, 2023 (vendor technical doc)[8][9]. *A commercially available robotic gripper using gecko-inspired dry adhesive pads. It requires no cables, electricity, or air supply to operate[8]. The gripper comes in three sizes (SP1, SP3, SP5) named by payload (1–5 kg) and can lift smooth, shiny, or even*

perforated objects (like circuit boards or mesh) without marking the surface[9]. The adhesive leaves no residue on high-gloss materials, eliminating post-process cleaning, and can repeatedly attach/detach in manufacturing tasks. This product shows that dry adhesion has matured into a **deployable tool in industry**, handling use-cases where traditional vacuum grippers fail (e.g. grabbing objects with holes or sensitive surfaces).\*

78. **Surface Adaptable and Adhesion Controllable Dry Adhesive with Shape Memory Polymer – S. H. Lee, M. K. Kwak et al.** – *Macromolecular Rapid Comm.*, 04/2022 (peer-reviewed)[10]. Demonstrates a shape-memory polymer (SMP) based dry adhesive that achieves ~332.8 kPa of shear adhesion on various surfaces, yet “turns off” to a low ~3.7 kPa when released by changing its shape[10]. The SMP micro-structures can conform to uneven surfaces and then recover, enabling both strong grip and easy release. The authors used this adhesive in a prototype glass-handling system to effortlessly pick and place an ultra-thin glass film, showing its potential for high-throughput electronics manufacturing. This validates the feasibility of mass production line use, with high adhesion strength and rapid switching comparable to – or exceeding – conventional methods.
79. **geCKo Materials Dry Adhesive (micro-wedge technology)** – geCKo Materials, PBC (startup) technical spec sheet, 2024 (vendor technical doc)[11][12]. A U.S. startup (spun from Stanford research) offers a micro-wedge dry adhesive that is ultra-strong, reusable, and residue-free. The product can hold about 120 kPa of shear stress and needs effectively zero force to attach or detach, mimicking gecko toe function[12]. It attaches/detaches within milliseconds and is rated for up to 120,000 reuse cycles with no performance loss[11]. The company reports having developed a scalable manufacturing process (proprietary) to produce the adhesive in quantity[13]. This indicates that **industry-grade durability and lifetime** (hundreds of thousands of cycles) are being achieved, and efforts are underway to **mass-manufacture** dry adhesive components at viable cost.\*
80. **LIZARD in-orbit adhesive experiment (TU Berlin)** – 14th IAA Small Satellites Symposium (conference paper), 05/2023[14]. Describes the “Long-term Investigation of Zero-g, Vacuum and Radiation on Gecko materials” (LIZARD) experiment: a CubeSat mission scheduled for launch in 2024 to test gecko-inspired adhesive samples in space for 1 year. It will measure how vacuum, thermal cycling, UV radiation, and atomic oxygen exposure affect adhesion performance over time[14]. Multiple dry adhesive material variants will be repeatedly pressed and peeled from a surface in orbit, with load cells recording grip forces. This large-scale durability study, supported by European research agencies, shows a push toward qualifying gecko adhesives for real-world deployment (e.g. satellite docking or debris capture), examining longevity and failure modes in operational environments.
81. **Shin-Etsu Chemical to acquire Setex (gecko adhesive company)** – *Indian Chemical News*, 04/23/2024[15][16]. Reports that Shin-Etsu Chemical, a global industrial materials firm, acquired Setex Technologies – a startup commercializing gecko-inspired adhesives (formerly NanoGriptech, maker of Setex “Geckotape”). Shin-Etsu plans to combine Setex’s micro-fibrillar adhesive (which provides strong friction/adhesion via a gecko-like surface) with its own materials to create “ShineGrip” solutions[15]. Target applications include semiconductor manufacturing processes and other industries requiring repeated attach-detach without residue[16]. This is evidence of a **well-capitalized market actor investing in dry adhesion tech**: a major chemical company is betting on scaling up and applying gecko adhesives in high-value manufacturing, which signals confidence in the technology’s commercial potential.\*
82. **Controlled Dry Adhesion of Bio-Inspired Fibrillar Polymers: Mechanics, Strategies, and Recent Advances** – M. Alizadehyazdi et al. – *Bioengineering (MDPI)*, 2023 (peer-reviewed

review)[17][18]. Survey of recent advances in switchable fibrillar adhesives focusing on engineering challenges like contamination and repeatability. It highlights an approach by Alizadehyazdi et al. where a piezoelectric element was embedded with a gecko-inspired adhesive to actively shake off dust particles and concurrently serve as a contact force sensor[17]. This setup allowed the adhesive to be “turned off” via ultrasonic vibration for cleaning/tuning adhesion. Another case discussed is a hierarchical gecko-like adhesive with embedded magnetic particles that achieved self-cleaning and could even handle ultra-light objects when activated by a magnetic field[18]. These examples show that researchers are solving practical issues (dust fouling, mode of release) and integrating adhesives into multi-functional systems, improving reliability for real-world conditions.

### 3. Maturity score (1–7) and reasoning

#### Overall ART maturity score: 5 (Prototype/Demonstration phase).

**A) Justification of score:** The accumulated evidence shows that gecko-inspired dry adhesion has **progressed beyond laboratory proofs (Levels 2–3)** to working prototypes and initial commercial products. For example, a **market-ready gecko gripper is being sold and used in industry** (OnRobot’s device) – a strong sign that the core technology works under real conditions, **surpassing a mere proof-of-concept**[8][9]. Multiple academic groups have recently demonstrated **key performance breakthroughs** such as rapid switchable adhesion[3], integrated sensing[1], and extreme durability ( $10^5+$  cycles)[11], indicating that previously blocking issues (slow release, lack of feedback, short lifespan) are being solved. These achievements collectively **rule out maturity Levels 1–3** (the concept is well beyond theory or single lab tests). The technology as a bundle is now around Level 5: there are **functioning prototypes meeting functional requirements** and clear advantages over incumbents, with **active investment to commercialize them**. For instance, the Shin-Etsu acquisition of Setex in 2024 shows that **well-capitalized industry players are entering the race**[15], aiming to scale production and deploy gecko-adhesive solutions in manufacturing – behavior characteristic of Level 5. Recent field trials, like NASA’s ISS demo, further validate the technology in challenging environments[7], signaling that gecko adhesives are no longer confined to the lab.

However, evidence for Level 6 (broad product delivery and scaling) is still **emerging rather than fully realized**. While one or two products exist, we do not yet see **wide competition with multiple suppliers or high-volume adoption across industries**. The OnRobot gripper addresses niche use-cases and startups like geCKo Materials and Setex are just transitioning to scale; we don’t have reports of millions of units shipped or sharply dropping costs yet. Furthermore, **certain sub-systems remain at prototype stage** – e.g. wall-climbing robots using these adhesives are still mostly experimental, and full integration of sensing + adhesion in a commercial device is likely a next step. Thus, the ART hasn’t reached Level 6 “customer-delivered products in increasing volumes” across the board. Its trajectory is upward, but **some reliability and generality challenges (rough surface performance, self-cleaning, etc.) are still being actively researched**[17][18], preventing a jump to mass deployment in all scenarios. The score of **5** reflects a technology bundle on the cusp: proven in demos with clear use-case value, supported by significant R&D and early commercialization, but still maturing in manufacturing scale and breadth of adoption needed for the next level.

**B) Sub-component breakdown:** Since the ART consists of multiple integrated elements (materials, mechanisms, applications), their maturities vary:

- **Dry adhesive materials: Level 6.** The core adhesive films/pads themselves are quite advanced – one company has delivered them as a product (Setex’s Geckotape, OnRobot pads) and achieved large-scale fabrication runs. They offer high strength (100+ kPa) and long lifetimes[12][11]. The **acquisition of Setex by a major chemical company**[15] underscores that adhesive *materials* are entering commercialization and being internally funded by industry (a Level 6 trait).
- **Adhesive-based grippers/manipulators: Level 5–6.** OnRobot’s gecko gripper (launched ~2019 and updated through 2023) is being sold worldwide, indicating a working **production prototype** in use. No direct competitor product is widely known yet (OnRobot is somewhat unique), but the presence of at least one **established vendor shipping units** and startups preparing competing offerings (e.g. ShineGrip from Shin-Etsu) suggests a transition from Level 4 to **Level 5+** for manipulation applications. This segment benefits from relatively controlled environments (flat parts, indoor factories), making commercialization easier.
- **Climbing robots / mobility systems: Level 3–4.** Attaching robots to walls or ceilings via dry adhesion has been demonstrated in labs (e.g. *Stickybot*, *UNiclimb*) and specialized trials (astronaut tests on ISS) but **not yet productized** for broad use. Issues like uneven surfaces, dust, and safety have kept this sub-application mostly in prototype stage[17][18]. No off-the-shelf wall-climbing robot using gecko pads is on the market as of 2025. Thus, mobility use-cases lag behind grippers, roughly at proof-of-concept Level 3–4 (working demos, but not routine deployment).
- **Sensing and control integration: Level 3.** The fusion of dry adhesives with embedded sensors and smart control (for auto-tuning preload, etc.) is very new – e.g. the self-sensing pad from 2025[1]. This is at a **lab prototype** stage (TRL 3) with clear functionality shown, but not yet in products. It will likely advance in the next few years as these intelligent adhesives are tested in pilot projects.

Considering these sub-scores, the **overall functionality spans from mid/high to early stages**. The **core adhesive tech and basic gripper use** are at a higher maturity (approaching early commercial rollout), while more complex integrated systems (climbing robots, smart adhesives) are a step behind. The **total value of the ART comes from combining these elements**, so the bundle’s maturity is best represented by an **average** of the parts rather than the maximum. By averaging the above:  $(6 + 5.5 + 3.5 + 3) \approx$  **approximately 5**, we arrive at a composite Level 5. This aggregation reflects that the **fundamental capability is proven and entering the market (thanks to sub-components at ~5–6), but full integration and widespread adoption are still in progress (due to components at ~3–4)**.

## Group 6 – Additive, Agile & Digital Manufacturing

### ART 06.037 Multi-Material & Hybrid 3D Printing

#### 83. ART extraction

84. *Primary capability:* Additive manufacturing systems that can **print complex parts using multiple different materials in one build**, combining polymers, metals, ceramics, and conductive inks in a single 3D printing process. This enables fabrication of entire functional assemblies in one step, with integrated mechanical, thermal, and electrical features that traditionally require separate manufacturing and assembly steps.

85. *Key sub-components/variants:*

- **Polymer–Metal Hybrid Printing:** Processes that print plastic and metal together (or sequentially) to create lightweight parts with embedded metal reinforcement or circuitry. For example, using dual extrusion or print-and-plate techniques to integrate conductive metal pathways into polymer structures.

- **Multi-Metal & Graded Alloy Printing:** Techniques (e.g. multi-material powder bed fusion or directed energy deposition) that combine different metal alloys in one part or create functionally graded metal components (one metal transitioning to another), providing locally tailored strength, conductivity, or heat resistance.
  - **Polymer–Polymer & Composite Multi-Material:** Multi-nozzle or multi-resin printers that deposit different polymers (rigid, flexible, elastomeric, colored, etc.) in one object, as well as composite printers that embed continuous fibers (carbon, glass, Kevlar) into thermoplastic parts for enhanced stiffness.
  - **Embedded Electronics Printing:** Integrating conductive inks, pastes or wires during printing to embed **electrical circuitry, sensors, antennas, or connectors** directly inside structural parts. This often involves hybrid systems (e.g. combining material extrusion with direct-ink writing or aerosol jetting) to print insulating structural material and conductive traces in one job.
  - **Hybrid Additive–Subtractive Systems:** Machines that **combine 3D printing with secondary processes** like CNC milling, laser machining, or pick-and-place. These hybrids can deposit material and then mill surfaces or drill channels in situ, enabling precision features, smooth finishes, or insertion of components during the build.
86. *Maturity indicators:* Evidence of **working prototypes and commercial systems** that print multiple materials in one go (e.g. demo parts with integrated metals and polymers, or electronics). Reports of **functional parts printed with multi-material AM** (e.g. a 3D-printed device with embedded circuits or a graded metal part with improved performance) indicate scientific feasibility. The emergence of **commercial printers or spin-offs** offering multi-material capabilities, **pilot production or field demonstrations**, and **multiple companies investing in development** would signal progress toward commercialization. Key milestones include proof that multi-material parts meet performance requirements (strength, conductivity, etc.) and that **process control challenges (bonding between materials, calibration)** are being solved, as well as evidence of **investment, partnerships, or early customer adoption** of such systems.
87. **Evidence (10–20 recent, reliable sources)**
88. *Fraunhofer IKTS / AMAREA – Multi-Material Jetting Platform (Press release, 09/2023):* Researchers at Fraunhofer IKTS (Germany) spun off a company (AMAREA Technology) to commercialize a **multi-material inkjet 3D printer** that can combine up to **six different materials (ceramics, metals, glass, polymers, etc.) in one print**. They demonstrated convincing prototypes for industrial clients and plan a 2024 market launch of a printer with six printheads (achieving ~70–100 µm accuracy and 8–12 cm<sup>3</sup>/h per head). An optional in-line laser module will even polish or machine surfaces during printing[1][2]. *This shows a well-supported effort to bring multi-material printing (including ceramics and metals together) to commercial reality, with funding and a roadmap for scaling.*
89. *Lithoz CeraFab Multi 2M30 – Metal/Ceramic/Polymer Printer (Trade news, 10/2023):* Lithoz (Austria) unveiled a new multi-material 3D printer (CeraFab Multi 2M30) capable of **printing ceramics combined with metals or polymers in one part, even within a single layer**[3]. They displayed **functional multi-material parts (including embedded electronic devices)** at Formnext 2023. *This provides evidence of an industrial AM machine achieving in-situ combination of vastly different material classes (e.g. insulating ceramic with conductive metal), indicating the technical feasibility of tightly interleaving materials during a single build.*

90. *DMG Mori LASERTEC 65 DED Hybrid – Multi-material metal + machining (Industry news, 10/2022)*: Machine-tool leader DMG Mori demonstrated a **hybrid directed-energy deposition (DED) machine** that can deposit metal and then mill it in the same setup. For example, a LASERTEC 65 DED Hybrid was used to 3D-print a copper or bronze core with internal cooling channels, **machine precision channels**, then deposit a tool-steel outer layer – all in one continuous process[4]. *This showcases multi-material metal printing (two different alloys in one part) combined with in-situ machining, proving out a key hybrid capability: making parts like molds with one metal embedded in another, something impossible via conventional methods.*
  
91. *Griffis et al. – Multi-Material Laser Powder Bed Fusion Demo (npj Adv. Manufacturing, 03/2025)*: A research team (Penn State and collaborators) **demonstrated multi-material laser powder bed fusion** by selectively depositing different metal powders in one build. They printed a complex gyroid structure composed of **904L stainless steel and bronze** in a single job, and analyzed the melt-pool, interface microstructure, and mechanical performance[5][6]. The study showed both the **opportunities and challenges** of MM-LPBF: such as achieving good bonding at the material interfaces and managing defects, with potential applications in thermal-management surfaces and biomedical implants. *This provides experimental proof that high-resolution metal 3D printers can fabricate graded or discrete multi-metal parts, though it also underscores remaining issues (e.g. cracks, property mismatches) when fusing dissimilar metals.*
  
92. *Zhu et al. – 3D Printed Soft Robot with Embedded Electronics (Science Advances, 12/2025)*: Researchers from Shanghai Jiao Tong Univ. and NTU Singapore reported an **integrated Digital Light Processing (DLP) + direct-ink writing** system to fabricate soft robots with electronics in one go. They printed soft silicone structures *and simultaneously* printed stretchable conductive inks as wires and sensors within the body[7]. The result was autonomous soft robots with **embedded tactile sensors, antenna for wireless communication, onboard actuators, and even obstacle avoidance capability**, all produced without manual wiring[8]. *This peer-reviewed work demonstrates the plausibility of printing functional devices (in this case, robots) that come out of the printer already containing working circuits and sensors, a key promise of multi-material AM.*
  
93. *Wilt & Lewis (Harvard) – Printed Soft Actuators with Internal Channels (Advanced Materials, reported 02/2026)*: A Harvard research team developed a **rotational multi-material printing method** using a single coaxial nozzle to deposit two materials at once[9][10]. They printed soft robot structures with a polyurethane elastomer as the exterior and a fugitive ink (poloxamer gel) as the interior. After printing, the sacrificial core was washed out, leaving **complex internal channels** in the part[10]. When these channels were pressurized, the structures achieved **programmable bending and motion** without any assembly[11]. *This innovation shows how multi-material deposition (structure + sacrificial material) can create integrated fluidic actuators in one step, eliminating the need for molds or assembly of soft robotic components.*
  
94. *Patadiya et al. – Multimaterial AM Review & Antenna Example (ACS Applied Eng., 2025)*: A comprehensive 2025 review on multimaterial additive manufacturing noted rapid progress in multi-nozzle and multi-ink systems. For instance, it describes a commercially available **nScript 3Dn-300 multi-material printer** (FDM plus micro-dispensing) that was used to fabricate a functional low-profile **antenna** by printing one dielectric material (polycarbonate) and simultaneously depositing a conductive silver ink trace[12]. *This example highlights real-world functionality: a fully printed RF device with integrated conductors, demonstrating that multi-material printers are already yielding working components (antennas) that meet electrical performance goals.*

95. *Nano Dimension DragonFly IV – 3D Printed Electronics System (Vendor technical doc, 06/2023)*: The DragonFly IV is a commercial additive electronics printer that **simultaneously deposits conductive metal (silver nanoparticle ink) and insulating polymer** to build complex circuit boards and radiofrequency devices layer by layer. Nano Dimension’s press release notes this system can **fabricate in-situ capacitors, coils, antennas and transformers** by printing conductive and dielectric materials together[13]. It has been adopted by research institutes (e.g. University of Stuttgart) for developing next-gen quantum sensor hardware. *This provides evidence of a shipping product enabling multi-material (metal-polymer) printing, albeit applied to electronics: it underscores that tightly integrated multi-material printing is commercially feasible in a niche (PCB/prototyping) and is now spreading to advanced R&D applications.*
96. *Zhang et al. – Continuous Fiber Composite 3D Printing (Composite Structures, 06/2023)*: A 2023 study optimized 3D printing of **continuous carbon fiber reinforced polymer** parts. By tailoring fiber orientation and topology, they achieved **256% higher stiffness and 305% higher strength** compared to standard Markforged printed composites[14][15]. Markforged’s existing printers already combine nylon with continuous carbon fiber to produce “**metal-strength**” composite parts, and this research shows the performance can rival aerospace-grade aluminum[15]. *This illustrates a mature subset of multi-material AM – continuous fiber reinforcement – which is commercially deployed. The ability to print a polymer part with embedded fibers for local strength is a concrete (and successful) example of tailoring material properties within a print, aligning with the ART’s claims.*
97. *Npj Review – Challenges in Metal-Polymer AM (npj Adv. Manuf., 2025)*: A recent review on heterogeneous metal–polymer additive manufacturing noted that **combining metals and polymers in one structure remains fundamentally challenging** due to their disparate properties (thermal expansion, melting points, etc.), which has historically limited progress[16]. Nonetheless, it highlights broad interest from aerospace to biomedical sectors in overcoming these issues[17]. *This underscores that while multi-material printing is scientifically plausible (as shown by lab demos), materials compatibility is a key hurdle. It validates the ART’s note that material compatibility windows and interface bonding are critical constraints, thus framing current R&D focus areas that need to be solved for full maturity.*

#### 98. Maturity score (1–7) and reasoning

#### Overall Maturity Score: 4 (Proof-of-Concept)

**A) Justification for score:** Multi-material & hybrid 3D printing has clearly moved beyond theory (Levels 1–2) and basic lab demos (Level 3) into the **proof-of-concept and early prototype stage (Level 4)**. Strong evidence shows **functional prototypes** and even niche commercial products: for example, researchers have printed working devices like antennas[12], electronic soft robots[7], and soft actuators[11] entirely via multi-material AM, proving the core functionality is achievable. Key technical barriers such as multi-material powder bed fusion have seen breakthrough demos (e.g. steel–bronze parts[5][6]), indicating that previously blocking problems (like fusing dissimilar metals) can be solved in principle – a hallmark of reaching Level 3. We even have **first-generation commercial systems**: continuous fiber printers and 3D electronics printers are on the market, and a six-material ceramic/metal printer is launching (Fraunhofer’s AMAREA, 2024)[1][2]. These achievements collectively **exceed Level 3** because they meet functional requirements in real applications (strength of composites rivaling metal[15], printed circuits functioning at GHz frequencies, etc.). However, the technology is **not yet widely adopted or broadly commercialized**, which holds it at Level 4. We do not see multiple major manufacturers shipping general-purpose

multi-material machines in high volume – instead, the field is still characterized by isolated specialized systems and ongoing R&D. There is growing investment and competition (a positive sign toward Level 5), such as new entrants (start-ups, spin-offs, and established AM companies like Lithoz, DMG Mori, Stratasys, Nano Dimension, etc.) developing multi-material capabilities. But these efforts are just coalescing now, with most products in beta or low-volume production. The **remaining gaps** (material incompatibilities, process stability, cost and speed limitations) are widely acknowledged[16] and no vendor yet offers a mature, turnkey “print-all-materials” solution for broad industry use. Thus, the evidence best fits a **Level 4 PoC stage**: the concept is proven viable with prototypes meeting key functionality, and it’s poised to move toward commercialization once scalability and reliability improve.

**B) Evidence ruling out lower levels:** The reported accomplishments clearly transcend a purely theoretical or early-experimental stage. Level 1/2 are ruled out by the numerous **experimental demonstrations in the last few years** – e.g. printing **fully integrated functional objects** (soft robots[7], RF antennas[12], multi-material lattice structures[5]) that work as designed. Level 3 (lab prototype solving a key hurdle) has been surpassed as well – for instance, the **DragonFly IV printer is already delivering multi-material electronic devices to paying customers**[13], and **Markforged’s multi-material composite printers are deployed in industry**, indicating viability beyond one-off lab prototypes. The breadth of actors (academic groups, government labs, start-ups, and established companies) all pushing this technology further also suggests we are beyond a singular prototype – the concept has momentum and **multiple proof-of-concept implementations** in different domains (electronics, aerospace, biomedical, etc.).

**C) What’s missing to reach higher levels:** To progress to Level 5 and above, we would expect to see **multiple well-capitalized firms racing to productize multi-material AM**, and evidence of reliable production-grade machines entering the market. While we do see early market entrants (spin-offs like AMAREA, and companies like Nano Dimension or Stratasys in specific niches), the field lacks a **general, high-volume solution** so far. There isn’t yet a fully **scalable, cost-effective multi-material printer** that can, for example, replace multi-step manufacturing lines for a broad range of parts – current machines are either limited in material combinations, have slow throughput, or require highly controlled conditions and expert operators (as noted in the ART description). To reach Level 5–6, the technology needs: improved material compatibility (strong bonding between disparate materials, without manual intervention)[16], **higher reliability and calibration** for complex builds (some evidence, like the need for careful control in metal-polymer printing, shows this is still being worked out[18]), and **economic viability** for more than specialized low-volume use. We would also expect to see **expanding adoption** – e.g. more companies purchasing multi-material machines for production, and perhaps standards or supply-chain integration – which has only just begun. In summary, the **functionality has been proven (Level 4)**, but **scaling and commercialization** are in early days; with continued progress, the technology could soon enter Level 5 (multiple competitive prototypes approaching market). For now, it remains a promising proof-of-concept with clear practical demonstrations but limited deployment.

## ART 06.038 Digital Twin & Simulation-Driven Production

### 99. ART extraction

100. **Primary capability:** Real-time digital duplication of each significant manufacturing asset or process, allowing continuous monitoring and **simulation-driven optimization** of production operations. This enables testing of changes virtually (at accelerated timescales) before implementing them in the physical factory, thereby improving control over complex processes and decision-making.
101. **Key sub-components/variants:**
- High-fidelity *physics-based models* of equipment and processes, combined with data-driven surrogate/AI models to mirror and predict the system's behavior.
  - **Real-time sensor integration and data streaming** (Industrial IoT) from physical machines to their digital twins, providing up-to-date state information.
  - **Digital thread connectivity** linking physical and virtual counterparts (e.g. via industrial protocols) for bidirectional control and feedback.
  - **Simulation and virtual commissioning tools** that test process changes, new product introductions, scheduling scenarios, or maintenance actions in a virtual environment (including 3D visualizations and AR/VR dashboards) without disrupting real production.
  - **Automated control agents and AI** that can autonomously adjust process parameters within safety/quality constraints, using the twin to evaluate outcomes and continuously learn and calibrate models.
  - **Infrastructure and integration** elements such as edge/cloud computing resources to run simulations in sync with operations, and adapters for legacy equipment to participate in the digital twin ecosystem.
102. **Maturity indicators for evidence:**
- **Field pilots & deployments:** Documented *proof-of-concept demonstrations in actual production lines* or factories, showing that digital twin systems function at scale and yield improvements (e.g. reduced downtime, improved throughput or quality).
  - **Commercial platforms & industry adoption:** Availability of vendor-supported **digital twin platforms or toolkits** (from major industrial tech firms) and case studies of **multiple well-funded companies implementing digital twins**, indicating competition and investment in the technology.
  - **Performance benchmarks:** Empirical results showing the twin technology's feasibility (e.g. real-time co-simulation achieved, predictive accuracy improvements, optimization outcomes) and clear *benefits over traditional methods* (such as faster ramp-up or cost savings in production).
  - **Standardization and consortia:** Presence of **industry standards (ISO, etc.)** and large research or government programs dedicated to digital twins (signifying consensus on frameworks and significant R&D funding), as well as efforts to integrate the technology into **workforce training and best practices**.
103. **Evidence (10–20 recent, reliable sources)**
104. *Digital twin driven smart factories: real time physics based co-simulation using edge a.i. and federated learning* – V. Padmavathi et al., Scientific Reports (peer-reviewed), Dec 2025.  
**Findings:** Proposes an edge-computing digital twin framework for manufacturing that combines physics simulation with federated AI. In testing, it achieved **35% lower latency and**

**a 13.2% throughput increase** compared to a cloud-only baseline[1], demonstrating feasibility of real-time, scalable co-simulation for factory processes. (Shows plausibility of fast, AI-enhanced twins for on-site control.)

105. *A Digital Twins Platform for Digital Manufacturing* – **Maheshi Gunaratne et al. (Swinburne Univ.)**, *Electronics* (MDPI journal, peer-reviewed), Jan 2026. **Findings:** Introduces a comprehensive digital twin framework (physical twin + virtual twin + digital thread) and platform for production lines. A **case study in composite airframe manufacturing** is presented where sensor-fed AI models in the twin predicted product quality and **cut curing time for a composite part**, improving efficiency while maintaining quality[2]. (Demonstrates a working prototype that integrates real-time shop-floor data and modeling to optimize an advanced manufacturing process.)
106. *Digital twin system for manufacturing processes based on a multi-layer knowledge graph model* – **Chang Su et al.**, *Scientific Reports* (peer-reviewed), Apr 2025. **Findings:** Describes a knowledge-graph-based architecture to integrate heterogeneous data for a manufacturing digital twin. Validated in an **aero-engine blade production line**, the system improved part precision (maximum contour error reduced from 0.073 mm to 0.062 mm) and raised the yield (qualification rate from 81.3% to 85.2%) over 5 months[3]. (Shows a deployed digital twin improving quality control and anomaly detection in a real production process.)
107. *Digital twin key technology on rare earth process* – **Hui Yang et al.**, *Scientific Reports* (peer-reviewed), Aug 2022. **Findings:** Explores applying digital twins in the *rare-earth extraction* industry (a complex chemical process with nonlinear, coupled variables). The paper presents methods for soft-sensor measurements, process simulation, and control optimization within a digital twin of a cascade extraction process. A **model validation and case study** confirmed the twin's feasibility in simulating the process and predicting failures[4], suggesting the approach can improve efficiency and fault management in process industries.
108. *Digital Twins for predictive maintenance: A case study for a flexible IT-architecture* – **P. Mrzyk et al.**, *Procedia CIRP* (conference proceedings), 2023. **Findings:** Investigates a standardized, reusable software architecture for deploying digital twins in different scenarios. The team built a flexible IoT and service-oriented architecture and applied it to **two use cases (a compressor and a wind turbine)** for predictive maintenance. They demonstrated that much of the integration could be reused between cases, **reducing the effort to build new digital twins** by leveraging a common architecture[5]. (Supports plausibility by addressing integration costs, and shows progress toward scalable twin deployments across equipment types.)
109. *BMW Group scales Virtual Factory* – **BMW Group (press release)**, Jun 2025. **Findings:** Reports that BMW has **implemented digital twins for over 30 production sites worldwide** as part of its “Virtual Factory” initiative[6]. This virtual commissioning environment allows planners to simulate factory changes and new vehicle integrations entirely in software. A notable result is that a collision-check process which once took ~4 weeks of physical tests now takes **3 days via the digital twin**, and BMW projects **30% lower planning costs** using these tools[6][7]. (Demonstrates an advanced real-world deployment: digital twin technology is actively used at enterprise scale to reduce time and cost in production planning.)
110. *Manufacturing Digital Twin Standards* – **Guodong Shao (NIST)**, EDTconf 2024 (conference paper), Sept 2024. **Findings:** This paper (from the U.S. National Institute of Standards and Technology) surveys digital twin use cases and challenges in manufacturing, and reviews ongoing **standardization efforts**. It highlights the new **ISO 23247 Digital Twin Framework for Manufacturing** and maps out a standards roadmap[8]. (Significance: Indicates

that industry and standards bodies are actively defining interoperability and best practices for digital twins, a sign of maturing technology and consensus on implementation approaches.)

111. **CHIPS Manufacturing USA “SMART” Institute for Digital Twins – U.S. Dept. of Commerce/NIST press release**, Nov 2024. **Findings:** Announces a \$285 million award (as part of a \$1 billion public-private effort) to establish “**SMART USA**”, a national institute dedicated to digital twin technology in semiconductor manufacturing[9]. The institute’s goals include using twins to **cut chip production costs >35% and cycle times ~30%**, and training 100k workers on twin tech[10]. (This represents a major government-backed investment in scaling digital twins, underlining both the feasibility and the expected economic importance in a critical industry.)
112. *Economics of Digital Twins: Costs, Benefits, and Economic Decision Making – Douglas Thomas (NIST)*, NIST Advanced Manufacturing Series report, Oct 2024. **Findings:** Analyzes the cost-benefit tradeoffs of digital twin adoption in manufacturing. It concludes that under plausible conditions, implementing digital twins could yield on the order of **tens of billions of dollars in annual value** across the industry (estimated ~\$37.9 billion potential, with a median scenario of ~\$27 billion)[11]. (This provides an economic rationale for the technology, showing that even with uncertainties, the productivity and efficiency gains make a strong business case as the technology matures.)
113. *Digital Twin for Flexible Manufacturing Systems and Optimization Through Simulation: A Case Study – Adriana Florescu, Machines* (MDPI, peer-reviewed), Nov 2024. **Findings:** Describes creating a digital twin for a real flexible manufacturing cell (robotic machining of cylindrical parts). The virtual model mirrored each device in the cell, enabling both time-based and discrete-event simulations. This allowed the team to **identify equipment collisions and errors in the system and test optimized solutions (like adding collaborative robots) virtually**[12], before physical implementation. (Demonstrates practical *virtual commissioning*: using a digital twin to detect design flaws and improve a production system, proving the concept can prevent costly mistakes and optimize layouts in advance.)
114. **Maturity score (1–7) and reasoning**

**Score: 6** (on the 1–7 scale). This score reflects that *Digital Twin & simulation-driven production* is transitioning from successful prototypes and pilots into **early industry-scale adoption**, with multiple major players delivering solutions, but not yet a fully ubiquitous commodity across all of manufacturing.

- **Why not lower:** The technology is well past the basic research stage (Levels 1–3). **Lab validations and pilot projects** have been abundant – for example, high-fidelity digital twins with real-time control have been demonstrated in research (e.g. real factory testbeds achieving performance gains[1]). More importantly, there are now **real-world production implementations**. BMW’s deployment of digital twins in 30+ plants shows that full-scale operational prototypes are in use, yielding tangible benefits (faster retooling, cost savings)[6]. The emergence of multiple **commercial offerings and active competition** (Siemens, GE, Dassault, PTC, etc., all marketing digital twin platforms) and large investments like the \$1B SMART USA institute[9] indicate the field has moved beyond isolated PoCs into a race for scalable products. These facts rule out Levels 4–5, which correspond to one-off prototypes or single-actor development; we already see **multiple well-capitalized actors and early customer adoption**, consistent with Level 6.
- **Why not higher:** The technology hasn’t yet reached the point where *digital twin systems are a standard, widely-installed solution across industry*, which would correspond to Level 7. While

demand and interest are rising, current adoption is still **uneven** – mostly in large enterprises or specific high-value sectors (auto, aerospace, semiconductors) and often in pilot/initial deployment phases. There is not yet a “plug-and-play” ecosystem of competing off-the-shelf products used by the majority of manufacturers. Key challenges remain (as noted by NIST[13]) in integrating legacy equipment, ensuring data interoperability, and building trust in these systems. Those challenges are being addressed (via standards like ISO 23247 and consortia), but until digital twins are as common as, say, traditional SCADA/PLC systems on every factory floor, the technology falls short of the saturation implied by Level 7. **In summary**, we have strong evidence of viability and scaling (widespread pilots, some full production rollouts, multi-billion-dollar investments), but *not yet the broad, mature market penetration* that defines the highest maturity level.

- **Sub-component considerations:** This ART actually encompasses a spectrum of capabilities – some are more mature than others. For instance, **virtual factory modeling and offline simulation** for production planning is already quite advanced (e.g. BMW’s virtual commissioning system, a Level~6 deployment). In contrast, **closed-loop autonomous control** via digital twins (where AI agents continuously adjust a live process) is earlier in adoption, perhaps around Level 4–5 in practice (proven in prototypes like predictive-maintenance twins[5], but not yet routine). Because these facets share the same overall goal (a data-driven cyber-physical production system) and are converging, the *overall maturity score is taken as ~6*. We chose Level 6 (competing products starting to scale to customers) since the core functionality – using digital replicas to optimize production – is already being delivered in industry with clear benefits, even if full self-optimizing “lights-out” factories (the ultimate vision) remain a few iterations away.

## ART 06.039 Reconfigurable & Agile Factories

115. **ART extraction**

116. *Primary capability* – “Reconfigurable & Agile Factories”: The ability to rapidly reconfigure production lines or workcells to handle different products or variations on demand, with minimal downtime or physical retooling. This enables factories to swiftly adapt to volatile demand, short product lifecycles, and high customization without sacrificing efficiency or quality.

117. *Key sub-components/variants*:

- **Modular robotic workcells** with standardized mechanical and digital interfaces. Each cell can incorporate robots, machine tools, conveyors, sensors, etc., as plug-and-play modules. End-effectors, fixtures, or process modules can be quickly swapped, and new “digital recipes” loaded, so the same physical cell can perform different tasks for different product families.
- **Rapid tool/changeover systems** (e.g. quick-release end-effectors, modular fixturing) that enable switching production tasks in minutes instead of lengthy line rebuilds. These hardware modules are supported by *universal interface standards* (akin to industrial “plug-and-play”) ensuring any new device or module can be integrated with minimal configuration[1][2].
- **Orchestration & planning software** that globally coordinates the modular cells. This includes model-based planning, optimization algorithms and digital **twin** simulations to schedule tasks, balance workloads, manage material flow, and automatically reconfigure the layout as needed[3][4]. The software leverages real-time data and AI to optimize production and can re-allocate resources on the fly when demand or conditions change.

- **Human-machine interfaces** that allow **high-level, intuitive control** of the factory. Instead of programming low-level machine code, human operators use visual dashboards, augmented reality (AR) overlays, or even natural language commands to specify desired outcomes and constraints. For example, voice- or text-based instructions to a Manufacturing Execution System have been tested (using large-language models) to execute multi-step production tasks[5][6]. AR overlays can guide technicians through reconfiguration or maintenance procedures visually.
  - **Infrastructure & standards** underlying the system: Reliable power and industrial networking are critical to link modules. New standards (e.g. the *Module Type Package, MTP*) are being adopted to define uniform **software interfaces** for modules, enabling true “plug & produce” integration across vendors[2][7]. Cybersecurity and safety frameworks are also crucial, given frequent reconfiguration could introduce new failure modes or attack surfaces.
118. **Maturity indicators/evidence to look for:** Concrete demonstrations of flexible factories in real settings (e.g. pilot production lines that make multiple products with quick changeovers), and **field trials or deployments** in industry. Key signs include proof-of-concept *pilot factories* or workcells showing hours→minutes reduction in changeover time, use of standardized module interfaces (with different equipment vendors interoperating), and **orchestration software** managing reconfiguration autonomously. Evidence of **commercial products** or platforms offering modular automation (and **investments** or competition between well-funded firms in this space) would indicate progression toward market readiness. Adoption of **standards** (like MTP or plug-and-produce protocols) by industry bodies, and **case studies** from manufacturing sectors (automotive, pharma, electronics, etc.) implementing such systems, would demonstrate both plausibility and growing maturity. Metrics such as reduced downtime, cost savings over product lifecycles, or smaller batch production made economically viable will be important. Also, watch for **government or consortium roadmaps** treating reconfigurable manufacturing as a strategic goal, and whether multiple suppliers offer compatible modular factory solutions (signaling an emerging ecosystem rather than a single lab prototype).
119. **Evidence (10–20 recent, reliable sources)**
120. **Assessment of design approaches for RMS (Rezaee & Moghaddam, *Computers & Ind. Engineering*, 2025) – Peer-reviewed journal paper (open access).** Proposes an integer linear programming model to optimally design and reconfigure a **Reconfigurable Manufacturing System (RMS)** over its life cycle based on demand changes[8]. Highlights the role of *modular reconfigurable machine tools* (RMTs) that can adjust capacity via module exchanges[9]. In simulation tests, predictive reconfiguration strategies (using accurate forecasts) minimized total costs, demonstrating that properly planned modular capacity adjustments can economically outperform static dedicated lines. This supports the *feasibility and cost benefits* of reconfigurable factories in coping with demand volatility.
121. **“A systematic methodology for changeable and reconfigurable manufacturing systems development” (Andersen et al., *J. of Manufacturing Systems*, 06/2024) – Peer-reviewed journal article (open access).** Presents a 4-step methodology for designing reconfigurable production systems, covering conception through implementation. Uniquely, it was **validated across seven real manufacturing companies**[10], integrating both existing and novel RMS design tools in collaboration with industry. The successful case studies demonstrate that companies in diverse sectors can adopt modular, changeable production methods in practice. This provides evidence of *practical feasibility*: the concept isn’t just

theoretical, but has been tested in industrial pilot projects, confirming that agile, reconfigurable factories can be realized with current technology and provide value across multiple environments.

122.     **Development of Reconfigurable Manufacturing (REKON Project, Denmark, 2020–2023)** – *Research consortium report (Aalborg Univ. & partners, funded by Danish Industry Foundation)*. A national initiative to help industries move from dedicated lines to **modular, platform-based production**[11]. Through pilot implementations in 7 companies (Phase 1) and broader dissemination (Phase 2), REKON developed a toolbox for designing reconfigurable production systems. Notably, it reports that prior research and pilot data showed reconfigurable production can **reduce capacity investment costs by up to 50%** compared to traditional dedicated lines, while still meeting demand uncertainty[12]. This economic result is compelling evidence that agile factories can significantly cut the cost of adapting to new products or volume changes, mitigating the risk of over- or under-capacity. (The project’s success also led to at least one journal publication from the team, underscoring its impact in both academia and industry.)
  
123.     **Audi Modular Assembly Pilot – Audi AG Press Release, July 2022** – *Industry press (automaker)*. Describes Audi’s implementation of the **world’s first modular assembly system** in automobile production as a pilot at Ingolstadt[13]. Instead of a fixed conveyor line, workers assemble door panels at independent “production islands,” with Automated Guided Vehicles (AGVs) delivering parts to each station on a flexible schedule. This modular approach allowed Audi to handle high product variability with ~20% efficiency improvement in the pilot (due to integrated logistics and inline quality checks)[14]. Crucially, it also enabled accommodating workers with different paces or disabilities by decoupling tasks from a rigid takt time. Audi’s pilot confirms the **technical plausibility** of reconfigurable production in a real factory: it achieved non-sequential, on-demand task routing and demonstrated improved flexibility and ergonomics. The fact that a major OEM invested in this and reported quantitative gains (20% efficiency) is a strong maturity signal (beyond lab demo, moving into production trial).
  
124.     **Automakers Embrace Modular Production for Flexibility (AMS, Aug 2025)** – *Automotive Manufacturing Solutions (trade publication)*. Reviews how major car manufacturers are adopting modular, “**matrix**” **production systems** to boost agility. For example, Jaguar Land Rover’s forthcoming Electrified Modular Architecture allows building a mix of EV and ICE vehicles on the **same assembly line**, enabling JLR to **pivot production in real time** as demand shifts without costly retooling[15]. Similarly, Audi’s use of flexible “production islands” served by AGVs is highlighted as a tangible result at its Ingolstadt plant[16]. The article notes multiple OEMs (BMW, Mercedes, Honda, Daimler Truck, etc.) now investing in such flexible manufacturing and supply chain setups[17]. This evidence shows *competition among well-capitalized actors*: the concept of reconfigurable/agile factories is being actively pursued by several global companies in parallel. It underscores that the industry views this as a key to resilience and efficiency (especially to handle EV transition and unpredictable markets), which speaks to increasing maturity (moving towards broad adoption).
  
125.     **“Plug and Produce — a review and future trend” (Khabbazi et al., Int. J. Adv. Manuf. Tech., Sep 2024)** – *Peer-reviewed review paper (open access)*. A comprehensive literature review of **Plug-and-Produce** concepts in advanced manufacturing control. It finds that over decades, researchers have greatly improved the *conceptual, logical, and physical* aspects of plug-and-produce, making integration of new machines or products ever faster and more seamless[18]. Modern implementations aim for **minimal downtime and no manual re-programming** when reconfiguring a production system – essentially treating manufacturing modules like plug-and-play peripherals[1]. The review identifies plug-and-produce as a

**foundational principle for future manufacturing**, aligning with Industry 4.0/5.0 goals, and notes that *standardization and industry consortia efforts are underway to support widespread adoption*[19]. In conclusion, it states the future of Plug & Produce is “promising” with active innovation and investment driving it forward as a key enabler of flexibility[20]. This source confirms the *scientific consensus* that the modular integration approach (a core enabler of agile factories) is feasible and maturing, backed by a growing body of experimental and standards-based progress.

126. **Festo Modular Automation & MTP (Festo AG, technical article, ~2023) – Vendor technical documentation (automation supplier).** Describes Festo’s solution for **decentralized, modular production systems** in process industries. Each process module is a standalone unit with its own control, capable of autonomous operation; modules connect via a standard interface called **Module Type Package (MTP)** that handles communication with a higher-level orchestration system[2]. This allows “plug & produce” flexibility – new modules (e.g. a filtration unit, reactor, filling station in pharma manufacturing) can be added or removed without reprogramming the whole system, and the orchestration layer automatically incorporates them[21][7]. The page highlights benefits like significantly faster commissioning (time-to-market *cut* ~50% in some cases) and easy capacity scaling by numbering-up modules instead of building a whole new line. It also notes Festo’s active role in standardizing MTP internationally (via VDI/NAMUR and IEC committees)[22], underscoring that major industry players are not only building products but also establishing *common standards* to make modular factories widely interoperable. This is concrete evidence of a *commercial toolset* for agile factories (Festo is delivering hardware/software for modular production), and the push toward standards shows an ecosystem forming (a hallmark of rising maturity).
127. **Merck & Siemens “Plug-and-Produce” Pilot Plant (NNE event brief, Oct 2022) – Industry case/consortium report.** Announces that **Merck KGaA** (a global pharmaceutical firm) is constructing a state-of-the-art production facility in Darmstadt using a *modular automation* approach[23]. The project, in close collaboration with Siemens, relies on the Plug & Produce concept with MTP and a Process Orchestration Layer (POL) standard. This initiative is presented in an industry event as a “gamechanger,” sharing real-world experiences of implementing MTP in a highly regulated environment. The significance here is that a *real production plant* (not just a demo cell) for pharmaceuticals – which demands high reliability and validation – is being built around reconfigurable, module-based automation. This indicates strong confidence in the technology’s **plausibility and readiness** for mission-critical applications. It also exemplifies cross-industry uptake (pharma, in addition to automotive), and suggests that by the mid-2020s, agile factory concepts are moving into *full-scale deployment* in at least pilot form.
128. **“Chat with MES”: Natural Language Control of Manufacturing (Yuan et al., J. of Manufacturing Systems, 2025) – Peer-reviewed experimental paper (open access).** Demonstrates an AI-driven interface where factory workers can interact with a Manufacturing Execution System using **natural language** (in this case, through a Large Language Model agent). The system, tested on a simulated garment factory, could interpret user requests (e.g. “change the production schedule” or “check machine status”) and break them into executable operations on the shop floor[5]. It achieved a **80% success rate** on 55 test queries, outperforming a baseline using raw GPT-4 (60% success)[6]. This proof-of-concept shows that emerging AI (LLMs) can make factory control more intuitive and “operator-friendly,” which is a key aspect of agile factories (operators specify high-level goals rather than low-level code). The results lend plausibility to the claim that *natural language or AR-based interfaces* can effectively augment human-machine interaction in reconfigurable production systems. While

still a research-stage result, it marks rapid progress in the HMI aspect, which will improve usability and reduce the expertise needed to reconfigure complex manufacturing setups.

129. **Digital Twin framework for Reconfigurable Manufacturing (Touckia et al., *Int. J. Adv. Manuf. Tech.*, Mar 2022)** – Peer-reviewed journal paper (open access). Introduces a **digital twin model** tailored for RMS, to aid in design and real-time reconfiguration of manufacturing systems[3]. The paper emphasizes that after COVID-19, companies recognize the need for quick reaction to market changes and see reconfigurable, agile manufacturing as a top priority[24][25]. It integrates advanced ICT (IoT, cloud computing, AI) to monitor the physical factory and simulate changes virtually, enabling faster adaptation (e.g., testing a new cell layout in the digital twin before physically reconfiguring). This is evidence of the *sophisticated software tools* being developed to support agile factories. It underscores plausibility: not only is the hardware being made modular, but the software (digital twin + AI) exists to validate and optimize reconfigurations, reducing risk and downtime. Such capabilities are essential for scaling up reconfigurable manufacturing, and the fact that this is an active research front (with industrial priority) indicates the field’s momentum.
130. **Essert “MicroFactory” Modular Automation Platform (Essert GmbH, product info, 2023)** – Vendor product documentation. Showcases a **commercial modular factory system** for the life sciences industry. The *MicroFactory Ecosystem* consists of process modules (“one process per module”) that can be docked together with a standardized **interface handling power, data, and logic** connections instantly[26]. This plug&produce design lets users start with a single automated module and expand to a full production line by adding modules as needed. Changeovers are very fast – the company claims adding or swapping a module can be done in **minutes**, whereas traditional changeovers take hours or days[27][28]. Importantly, when a new module is added, the rest of the line does not need re-validation, which is crucial for regulated manufacturing. This source is concrete evidence that *turnkey products* for reconfigurable, agile manufacturing are already on the market. An “award-winning” platform like this indicates that not only is the concept feasible, but it’s reaching customers (particularly in high-mix, high-complexity manufacturing like biotech/pharma) with promises of tangible benefits (faster scale-up, future-proof flexibility). It also exemplifies competition in the space – presumably, other firms will offer similar modular automation solutions if one company is successful, aligning with the emergence of an industry trend.
131. **Maturity score (1–7) and reasoning**

**Final Maturity Score: 5** (on the 1–7 scale).

**A. Justification – Evidence-to-Rubric Mapping:** The accumulated evidence places “Reconfigurable & Agile Factories” at **Level 5: early commercial prototype stage with multiple actors involved**. Lower maturity levels (1–3) are clearly surpassed – the core principles are *experimentally proven and demonstrated in working systems*. For instance, Audi’s 2022 pilot of a modular assembly line in a real factory environment shows a functional prototype solving prior blockers (flexibly decoupling assembly tasks from a fixed line) with measurable benefits[14][13]. Likewise, Merck’s collaboration with Siemens to build a modular production plant[23], and the existence of standardized module integration methods (MTP, Plug&Produce) adopted by industry, indicate that we are beyond isolated lab demos – the concept has moved into **practical trials and implementation**, satisfying at least Level 4 (Proof-of-Concept).

Several pieces of evidence push the assessment into **Level 5** territory. We see *multiple well-resourced organizations concurrently developing and investing in this technology*: e.g. major

automakers (Audi, BMW, JLR, Honda, etc.) are retooling production philosophies towards modular flexibility[17][16], major automation vendors (Siemens, ABB, Festo, Beckhoff) are offering products and standards for plug-and-produce[22][23], and even startups (like Essert's MicroFactory) are entering with modular automation solutions[26][28]. This competitive and collaborative momentum aligns with rubric Level 5, which is characterized by **well-capitalized actors racing to develop production-ready systems after a successful PoC**. Indeed, the evidence of cross-industry uptake (automotive and pharma pilots, among others) and the formation of consortia to standardize the approach shows that progress is recent and fast-paced. Each new prototype (e.g., the Merck modular plant or Audi's modular line) quickly motivates others, and standards like MTP are accelerating knowledge transfer – exactly the environment expected around Level 5 maturity. Notably, the technology also **meets or exceeds performance of conventional approaches in key areas**: e.g., Audi reported ~20% efficiency gains[14], JLR can avoid costly retooling by mixing models on one line[15], and modular systems can cut changeover time from days to minutes[28]. These advantages validate the commercial motivation and viability, suggesting the concept is on the cusp of wider adoption.

**B. Why not a higher score?** To reach Level 6 or 7, we would expect **broad market rollout and scaling**, with multiple competing products in regular industrial use and rapidly growing demand. While we have first products and pilots, *full production deployment is still limited*. Many of the implementations are pilot projects or initial phases (e.g., Audi's modular assembly was a trial in a sub-assembly, not yet an entire factory production, and Merck's plant is likely one of the first of its kind). We do not yet see evidence that hundreds of factories have converted to this paradigm or that “reconfigurable factory” solutions are routinely bought and installed at scale – rather, they are *in the introduction/early-adopter stage*. Additionally, some enabling sub-technologies are still maturing: for instance, **natural-language interfaces and AR control** for factories are just emerging from research (with a promising 80% success prototype[6], but not yet a standard feature on factory floors). Likewise, fully autonomous reconfiguration without expert engineers involved is not yet commonplace – some reconfiguration still requires careful planning (though digital twins and AI tools are coming, they are at early stages[4]). The need for further **validation, safety certification, and workforce training** in these systems means wide scale-up is likely incremental over the coming years. In short, the concept is proven and **entering commercialization (Level 5)**, but has not yet achieved the pervasive deployment or production volume growth that define Level 6.

**C. Sub-component maturity breakdown:** This ART is a bundle of several components, which are at slightly different maturity levels, though converging. The overall score **5** is mainly driven by the *core functionality* reaching a production-prototype stage, while acknowledging that some auxiliary aspects lag behind:

- **Modular hardware and integration platforms – Level ~5.** The physical modular workcells and the orchestration software that makes them function together have been demonstrated in industrial pilots and are offered by leading vendors. Evidence: Audi's and Merck's prototypes, Festo's and Siemens' module integration products, and the active standardization (VDI/VDE, IEC) indicate that the **industry considers this ready for near-term deployment**[23][2]. Multiple companies are building similar capabilities, confirming a competitive push at the cusp of commercialization.

- **Human-machine interface innovations** (AR, natural language control) – **Level ~3**. These are desirable for ease-of-use but not strictly required to achieve reconfigurable manufacturing. Current evidence (like the *Chat with MES* LLM interface) is at prototype stage in labs[6]. Some AR-assisted assembly or maintenance tools exist in factories, but natural-language operational control is not yet an established product. This sub-component is therefore less mature, around the stage of initial feasibility demonstrations (levels 2–3).
- **Autonomous planning and optimization (AI/digital twin) – Level ~4**. The software for automatically planning reconfigurations and optimizing production (using AI, simulations, digital twins) is under active development and has been piloted in some cases. For example, digital twin frameworks for RMS are being published and tested[3], and companies are using model-based scheduling in pilot projects. However, these tools are still advancing towards widespread robustness. They have cleared the basic R&D hurdle and shown clear utility, but need further refinement and integration for fully autonomous factory reconfiguration. This puts them at a proof-of-concept/early trial stage (around Level 4).

Considering these sub-scores, the *core capability* (modular, rapidly reconfigurable production) is solidly at **Level 5**, even if some supporting technologies trail slightly. The primary value of agile factories – quick physical reconfiguration and production agility – is already demonstrated with current industrial tech (robots, modular machines, orchestrators), and this justifies the higher weighting. The less mature aspects (like voice/AR control) don't prevent the concept's deployment; they will simply enhance it over time. Therefore, averaging the components would undervalue the fact that one can build a reconfigurable factory today using traditional HMIs and planning tools. **Hence, a score of 5 is assigned** – the concept as a whole is in the transition from proven prototype to early industry adoption. It's moving beyond the lab/PoC stage, but needs a few more years of scaling and ecosystem growth to reach full commercial maturation (Level 6).

## ART 06.040 Circular & Sustainable Manufacturing

132. **ART extraction**

133. *Primary capability:* Transform industrial **waste and end-of-life products into new manufactured components** in a continuous, closed-loop process, reducing reliance on virgin raw materials. This involves treating waste as a **primary feedstock** rather than a disposal problem, thereby decoupling production from volatile material supplies and lowering environmental impact.

134. *Key sub-components/variants:*

- **Automated in-line recycling & additive manufacturing:** Integrated systems for **sorting, breakdown, and re-fabrication** of scrap. Waste materials are mechanically or chemically broken down, **sensed and characterized in-line**, then **additively reprinted** into new parts with predictable properties.
- **Bio-based & recyclable materials:** New **engineered polymers, composites, and binders** derived from renewable biomass (e.g. plant sugars, oils) that are designed for **easy recycling or biodegradation**. Complemented by **bio-engineered materials** (e.g. mycelium composites, bacterial polymers) produced via **fermentation, biofabrication, or enzymatic assembly**, tuned for high performance but circular life cycles.

- **Low-energy transformation processes:** Use of **low-temperature methods** (e.g. cold sintering, photopolymerization, enzymatic or electrochemical fabrication) instead of traditional high-heat, batch processing. These reduce energy consumption and preserve material quality through multiple cycles.
  - **Digital integration & traceability:** A software layer connecting **digital product passports**, design tools, and production planning. This enables automatic adjustment of designs and process parameters to accommodate **variable recycled feedstock**, and provides **real-time data on material origin, composition, and history** for compliance and optimization.
135. *Maturity indicators:* We would look for **working pilot plants or prototypes** that demonstrate the full circular flow (from waste to new product) under realistic conditions. Evidence such as **proof-of-concept integrations** of sorting + additive manufacturing, **field trials or small-scale production** using bio-derived recyclable materials, and **commercial investments or offtake agreements** in these technologies indicate progress. Key signs include **products meeting quality specs made from recycled/bio feedstocks**, **regulatory frameworks (e.g. digital product passports) being implemented**, multiple **well-funded companies or consortia** pursuing the technology, and clear **improvements in cost, energy use, or material performance** compared to the status quo.
136. **Evidence (10–20 recent, reliable sources)**
137. **Ultrasonic recycling of metal powder in additive manufacturing – Sojoodi et al., Univ. of Toledo (Shape Memory and Superelasticity, peer-reviewed) – Oct 2025.** Open-access review detailing an **ultrasonic plasma atomization (UPA)** method to recycle NiTi alloy powder for 3D printing[1]. It shows that scrap NiTi can be converted into **high-quality spherical powder (sphericity >0.9)** with stable composition, and outlines an **industrial roadmap** using machine learning and closed-loop recycling to integrate this into additive manufacturing[1]. This demonstrates **technical feasibility** of circular reuse in metal printing and plans for scaling, supporting the ART's plausibility.
138. **AI-enhanced circular plastic recycling – Valle-Basagoiti et al., IPN Mexico (MDPI Polymers, peer-reviewed review) – Jan 2026.** Reviews advances in **mechanical, chemical, and biological plastic recycling** and how AI is boosting efficiency. Reports that **intelligent sensing (FTIR, Raman, hyperspectral imaging, LIBS) with ML classifiers** now significantly improve material identification and sorting precision (fewer rejects)[2]. AI-driven models also optimize depolymerization processes (e.g. pyrolysis catalysts, enzyme design), and case studies in Europe/Asia/LatAm show **digital traceability and producer responsibility** schemes are pivotal for circular outcomes[3]. The authors conclude that AI has become a “**structural enabler**” for transparent, optimized recycling systems rather than just a lab tool[4][5] – evidence that many pieces (sensors, data, automation) are in place to make circular manufacturing viable at scale.
139. **DOE workshop on circular plastics (U.S. DOE BETO/AMMTO report) – June 2023.** An authoritative workshop report highlighting recent **pilot-scale and commercial developments** in circular manufacturing for plastics. It notes that traditionally hard-to-recycle materials are now being addressed: for example, a “**Materials Recovery for the Future**” pilot **demonstrated optical sorting of flexible plastic packaging** at a recycling facility, and industry partners (Dow and Waste Management) launched a **curbside film plastics recycling pilot**[6]. The report also discusses emerging **digital tools for traceability**, including the **HolyGrail 2.0** trial of digital watermarks on packaging in Europe and calls for **Digital Product Passports**, to improve sorting and supply chain transparency[7]. These show that multiple

stakeholders are actively piloting **integrated recycling technologies and data systems**, indicating progress toward real-world deployment.

140. **EU Digital Product Passport mandate – European Commission (Policy, ESPR law) – July 2024.** The EU's new *Ecodesign for Sustainable Products Regulation* requires a **Digital Product Passport (DPP)** for nearly all goods[8]. The DPP is a digital record of each product's materials, origin, repair history, and end-of-life handling, accessible electronically to support sustainability and compliance[8][9]. This regulatory move directly supports circular manufacturing by ensuring **traceability of materials and components** and enabling automated recycling or reuse decisions. It reflects a **government-backed push** for the digital integration aspect of the ART, and major companies are now preparing to implement these passports by 2026.
  
141. **Integrated circular prototyping for electronics – TECOS & partners (SMART CIRCUIT pilot, EU Interreg report) – Dec 2025.** Final report of an EU pilot where an SME and research center **combined additive manufacturing with structured digital traceability** to enable circular design in electronics[10][11]. They established fast design–print–test loops focusing on **modularity, repairability, and reuse**, and **trialed recycled and bio-based polymer filaments** in 3D-printed electronic enclosures[12]. The results showed these **recycled/bio materials were viable alternatives to virgin plastics**, and the improved process (with digital BOMs and part labeling for future recycling) **reduced scrap rates and defects** during prototyping[13][14]. This provides real-world evidence that **circular manufacturing principles (materials + digital integration)** can be practically applied in industry with immediate benefits.
  
142. **High-performance recyclable biopolymer development – Gilsdorf et al., NREL/Colorado State U. (Cell Reports Phys Sci, peer-reviewed) – May 2024.** Demonstrates a new **bio-based plastic (vinyl lactone acrylic polymer)** designed for full circularity[15]. The team shows their polymers (PMVL and PMDL, from plant-derived monomers) have **high functional performance** (better solvent resistance and higher glass transition temperature than PMMA plastic) *and* can be **chemically depolymerized back to monomer nearly 100% under mild conditions**[15]. They achieved **reversible upcycling** of the material and performed techno-economic and life-cycle analysis, finding that **with efficient recycling, the bio-plastic could be cost-competitive and eco-competitive with conventional plastics**[15][16]. This is a concrete leap in sustainable materials – a **closed-loop polymer** proven in the lab, supporting the ART's claim that new materials can maintain performance through many recirculation cycles.
  
143. **Mycelium bio-composites for construction – Bonenberg & Sydor, Poznan U. Tech. (Materials, MDPI, peer-reviewed) – Jun 2024.** Reviews the state of **mycelium-based composites (MBCs)** grown from fungal networks as sustainable materials. It cites recent experiments where **growing mycelium in a knitted textile scaffold dramatically improved the mechanical strength** of the composite, enabling larger structural components[17]. The resulting bio-composites have a **hierarchically porous structure with high energy absorption and very low thermal conductivity**, making them viable **lightweight insulation or foam replacements**[18][19]. Crucially, MBCs are produced from **agricultural waste feedstocks, require little energy, and are fully biodegradable/compostable at end-of-life**[20]. This validates a key ART element: **bio-fabricated materials with good performance** (fire-resistant, insulating, load-bearing in this case) that can replace conventional synthetics and **return safely to nature**, although scaling up cultivation and standardizing quality remain challenges.

144. **Low-temperature recycling of composites via cold sintering – Randall Group, Penn State (university R&D demonstration) – Jan 2026.** A research team at Penn State has **demonstrated a “cold sintering” process to recycle composite materials** (like battery electrodes and fiber composites) at low temperatures[21]. Cold sintering uses a transient liquid phase under pressure to densify materials below 200 °C. The group showed this method can **reprocess composite waste into new usable forms without significantly degrading properties**, which is traditionally very hard for thermoset composites[21]. This is important evidence of a **novel low-energy process** that could handle materials (carbon fiber composites, etc.) that today end up as waste, moving a step closer to circularity in high-performance sectors (aerospace, EVs) where recycling is minimal.
145. **Energy-efficient electrochemical 3D printing – Sandia National Labs (R&D technical note, R&D100 Award) – 2023.** Sandia developed “**Electro 3D**” additive manufacturing, which uses localized electrodeposition to 3D-print metals at **room temperature and ambient pressure**, instead of laser melting[22]. This technique essentially miniaturizes an electroplating process into a print nozzle, allowing **high-resolution metal part fabrication with no furnace, no post-processing, and greatly reduced energy use**[22][23]. The process can rapidly switch materials and print on sensitive substrates, all while consuming far less energy (lower embodied energy, less CO<sub>2</sub>) than traditional metal printing or casting[23]. This supports the ART by showing that **alternatives to high-heat manufacturing** are becoming real – here a lab-scale proven method that could cut energy and enable new circular fabrication approaches for metal components.
146. **Commercial scale-up of bio-circular polymer (PEF) – Avantium N.V. (industry press release) – Aug 2025.** Avantium, a Dutch sustainable chemicals company, announced the start-up of the world’s **first commercial FDCA plant** (5 kT/yr) – FDCA being the monomer for **polyethylene furanoate (PEF)**[24][25]. PEF is a new **100% plant-based, recyclable polymer** designed to replace PET in bottles and packaging. The plant was officially opened in 2024 and is now being commissioned; Avantium expects **commercial product sales to begin in Q1 2026 under existing offtake agreements**[24]. This is strong evidence of **well-capitalized, real-world deployment** of a bio-engineered material central to circular manufacturing. A major company is investing in production and has customers lined up, aiming to deliver a high-performance plastic that can integrate into recycling systems. It shows the ART’s materials component moving from labs and pilots into **full production and market adoption** in the very near term.
147. **Maturity score (1–7) and reasoning**

**Final maturity score: 4** (Proof-of-Concept demonstrated as viable, with clear recent progress toward commercialization).

**A)** We assess *Circular & Sustainable Manufacturing* as a **bundle of innovations** and find that it exceeds laboratory demonstrations (Levels 2–3) and is entering the **proof-of-concept and early prototype stage (Level 4)** on multiple fronts. The evidence above shows **key functionalities proven in pilot settings**: e.g. an integrated pilot line reusing waste in electronics with measurable success[12][14], new bio-based polymers achieving **commercial-quality performance and recyclability** in research[15], and **pilot/commercial facilities** (5 kT scale) being built for novel circular materials like PEF[24]. These accomplishments indicate that the core scientific principles are solved and **practical viability has been demonstrated** in relevant environments – ruling out Levels 1–3. The NiTi recycling and plastic upcycling examples show the concept is not only possible but can **meet or beat traditional material specs**[1][15].

**B)** However, the integrated vision has not yet reached widespread product deployment or competitive scaling, which limits it below Level 5. **Missing evidence for Level 5+** includes: fully operational **end-to-end factories** converting mixed waste streams into new products at scale, or multiple corporations selling turnkey “circular manufacturing” systems in the market. While we see significant investment and some first commercial launches (e.g. Avantium’s PEF plant) suggesting rising competition, much of this ART is still in **isolated pilot projects and niche roll-outs** rather than an established industry. We do not yet have multiple vendors delivering complete circular manufacturing platforms or a broad adoption by manufacturers – the **activity is fragmented across sub-technologies**. For instance, one company might focus on bio-materials, another on recycling tech, but they are not all integrated into one mature supply chain yet. Regulatory drivers (like digital passports) are only just being enacted, and standards for circular use are in early stages. These gaps mean the concept as a whole has not fully transitioned to production-prototype or early market (which would be Level 5).

**C) Sub-component breakdown:**

- **Advanced recycling & sorting processes:** *Maturity*  $\approx 5$ . In plastics and metals recycling, multiple **well-funded companies and consortia are at pilot or commercial rollout stages**. Evidence: the DOE report notes **pilot and even commercial-scale advanced recycling tech** (optical sorters for films, chemical recycling startups) and significant investments by major firms[6][26]. This indicates a competitive push to scale these processes (approaching production prototypes and initial products, thus around level 5).

- **Sustainable materials (bio-based & bio-fabricated):** *Maturity*  $\approx 4$ . Many new materials are proven in labs and some are moving to **first commercial production**, but broad market adoption is just beginning. For example, the **recyclable bio-polymer (vinyl lactone acrylic) is at lab PoC** with economic analysis[15], and mycelium composites are functional at pilot scale[17]. Meanwhile, **PEF and similar bio-polymers are entering initial production** (the 2024 FDCA plant)[24] – a major step toward commercialization. On average this domain sits at PoC/early prototype stage – some materials at level 4 pushing 5, others at level 3 moving into 4.

- **Integrated manufacturing systems (additive + in-line reuse + digital):** *Maturity*  $\approx 3-4$ . This is the least mature aspect. We have **laboratory and pilot demonstrations** (such as the EU Smart Circuit pilot[10][12], or Sandia’s energy-saving metal printer[22]), which show the concept works and yields benefits. But these are still **one-off prototypes**; fully integrated factories with continuous reuse flows are not yet delivered. No large-scale product line is running on entirely circular, recirculating inputs today, to our knowledge. Thus this integration aspect is around a proven prototype (level 3) edging into PoC (level 4) in the best cases.

Given the above, we weighted the sub-components to arrive at an overall **Score  $\sim 4$** . The **scientific and engineering feasibility is well established**, and importantly, **recent pilot projects have solved key blockers** (e.g. maintaining material quality after multiple cycles[1], ensuring bio-materials meet performance specs[15], automating waste sorting with AI[2]). This rules out the lower levels. The technology bundle is on the cusp of broader implementation, but still **needs integration and scaling**. To reach Level 5, we would want to see multiple complete systems being built with significant private financing – for example, several companies marketing **modular circular factories or services**, or existing manufacturers retrofitting facilities to circular methods in competition. Once we observe **competing products and rising customer demand** for circular manufacturing solutions (e.g.

equipment, materials, software as a package) – signs of Level 5–6 – the score would increase. For now, the evidence best supports **Level 4: proven functional prototypes and clear recent progress, but not yet a mainstream commercial reality.**

---

## ART 06.041 Bio-fabrication technologies

### 1. ART extraction

**A. Primary capability** – Automated **bio-fabrication platforms** for producing human tissues and other biological products at useful scale. These systems integrate **3D bioprinting, engineered scaffolds, and controlled culture environments** to create living tissues with precise structure and composition, overcoming the limitations of manual cell culture.

**B. Key sub-components/variants** – - **High-resolution 3D bioprinters & bio-inks:** Print heads and “bioinks” (cells + biomaterials) to fabricate tissue constructs layer-by-layer with tunable architectures (including vasculature-mimicking channels).

- **Engineered scaffolds & biomaterials:** Supportive structures (hydrogels, polymers) that guide tissue formation, provide mechanical strength, and can be resorbed or integrated by cells.

- **Automated culture & bioreactor systems:** Incubators, perfusion bioreactors, and sensor arrays to maintain optimal conditions (nutrients, oxygen, temperature, mechanical stimuli) and scale up growth of printed tissues or organoids.

- **Integrated monitoring and control:** Sensors and software for real-time monitoring of culture parameters and automated adjustments to ensure reproducibility and quality (e.g. maintain sterility, prevent contamination, uniform cell growth).

- **Digital design & workflow software:** CAD-like tools for tissue design and recipe management, plus quality-control protocols. Remote updates can add new cell types, materials, or process workflows.

- **Product outputs:** *Tissue implants* (standardized patches, grafts, organoids with vascular channels and even embedded sensors), *cell-based reagents* (e.g. cultured cells or organoids for drug testing), and *bio-based materials* (engineered living or biomolecular products) produced with consistency and at scale.

**C. Maturity indicators** – Evidence to look for includes **peer-reviewed demonstrations of functional tissue prototypes** (solving prior blockers like vascularization or cell viability), **preclinical or clinical trials** of bioprinted tissues in animals or humans, **regulatory approvals or standards** emerging (e.g. first FDA clearances for bioprinted products, quality frameworks), and **commercial activity:** companies shipping bioprinters or tissue products, well-funded industry consortia, and multiple competitors racing to develop manufacturing platforms. Signs of maturity would be **production facilities** or “tissue foundries” coming online, **scaling metrics** (e.g. thousands of organoids produced automatically, large tissue constructs printed), and **investments/acquisitions** by major biotech or pharma firms indicating confidence in bio-fabrication technology.

### 2. Evidence (10–20 recent, reliable sources)

1. **From organoid culture to manufacturing: technologies for reproducible and scalable organoid production** – Dohui Kim et al. (*npj Biomedical Innovations*, review, 02/2026). This open-access review outlines the transition of organoid technology from lab technique to **industrial-scale manufacturing**. It details innovations for improving reproducibility and

throughput (e.g. micropatterned culture plates, droplet microfluidics, suspension bioreactors) and notes that regulators like FDA/NIH now recognize organoids as alternative preclinical models. It highlights that organoid-focused biotechs and pharma are rapidly adopting these platforms, marking a **pivotal shift toward standardized, high-fidelity organoid production with imminent clinical and commercial impact**[\[1\]\[2\]](#). It also describes emerging quality frameworks (OECD's GIVIMP) and the establishment of centers (NIH's SOM) to **promote robust, scalable organoid workflows**[\[3\]](#), underscoring the field's drive toward maturity.

2. **Semi-automated layer-by-layer biofabrication using rotational internal flow layer engineering technology** – Gwyneth West et al. (*SLAS Technology*, peer-reviewed, 04/2025). Researchers at University of Edinburgh demonstrate an **automation upgrade to a biofabrication process (RIFLE)** for building tubular tissues. The system automatically dispenses cell-laden hydrogel layers inside a rotating mold, achieving **high cell viability (>91% over 10 days)** and precise multi-layered structures (~14 µm thick cell layers) comparable to manual assembly[\[4\]\[5\]](#). This semi-automated platform reduced manual steps and human error in constructing vascular-like tubes, showing **progress in scaling up tissue engineering with reproducibility** and indicating that key technical barriers (layer resolution and viability at scale) are being solved in the lab.
3. **ARMI BioFabUSA “Tissue Foundry” Platform** – *Advanced Regenerative Manufacturing Institute (U.S. DoD Manufacturing USA program, info page updated 09/2024)*. ARMI's BioFabUSA consortium has developed the **first-ever scalable, modular, automated, and closed biofabrication line**, dubbed the Tissue Foundry[\[6\]](#). It consists of modules for each manufacturing stage of cell/tissue products, with robotics and sensors integrated for monitoring and controlling processes. The closed design (isolating the process from open air) minimizes contamination risk and reduces need for cleanroom facilities[\[7\]](#). This **prototype “tissue factory”** demonstrates the feasibility of end-to-end automation – from cell processing to tissue assembly – aiming to produce consistent, clinical-grade tissues at industrial scale. It validates the engineering integration described in the ART and shows that substantial capital investments (comparable to a mid-sized plant) are indeed being made to realize tissue manufacturing infrastructure.
4. **CollPlant and Stratasys Announce Pre-clinical Study for Regenerative Commercial-Sized Breast Implants** – *CollPlant Biotechnologies & Stratasys Ltd. (press release, 08/2024)*. This industry announcement details a collaboration in which a **bioprinted human-scale tissue implant (breast implant)** has been achieved. Using CollPlant's recombinant collagen bio-ink and a Stratasys Origin 3D printer, the team fabricated **200 cc volume implants** (approximate to an actual human breast) and began large-animal trials[\[8\]\[9\]](#). The goal is a regenerative implant that recruits the patient's cells to grow natural tissue and then biodegrades. Early preclinical results showed the 3D-printed implants can support **ingrowth of connective tissue and blood vessels** (neovascularization) and begin to biodegrade without adverse immune response[\[10\]](#). This demonstrates **scaling of biofabrication to clinically relevant sizes** and the involvement of well-capitalized partners; it underscores both the plausibility (functional tissues with vasculature printed) and advancing maturity (transitioning into preclinical trial stage for a commercial therapy).
5. **3D Systems launches Regenerative Tissue Program for personalized surgical reconstruction (press release)** – *3D Systems (corporate announcement, 02/2023)*. 3D Systems (a major 3D printing company) unveiled a program to commercialize **bioprinted human tissue solutions**, initially targeting a patient-specific **regenerative breast tissue scaffold (RBT™)** for post-mastectomy reconstruction[\[11\]\[12\]](#). The company leverages experience from its bioprinting of solid organs (ongoing projects on lung, liver, kidney) to create vascularized soft-tissue implants. The press release notes that in the past year they completed

multiple **large-animal proof-of-concept studies**, demonstrating an implantable scaffold that induces host tissue integration and blood vessel growth. Notably, they achieved both **host-mediated vascularization and direct surgical anastomosis of printed scaffolds** in these studies[13][14]. This indicates a **Proof-of-Concept (PoC) at commercialization criteria** – the printed adipose tissue scaffolds functioned well in vivo – and that a well-funded industry player is moving quickly toward a production prototype for clinical use.

6. **First-in-human trial of 3D-bioprinted ear implant (AuriNovo) – 3DBio Therapeutics & Microtia-Congenital Ear Institute (press release, 06/2022).** A clinical-stage biotech reported a **groundbreaking human surgery**: a 20-year-old patient received a 3D-bioprinted living ear implant (AuriNovo) made from her own cartilage cells, as part of an ongoing Phase 1/2 trial for microtia (ear deformity)[15][16]. The AuriNovo implant – a collagen hydrogel scaffold laden with the patient’s cells – was designed to precisely match her other ear. The FDA granted it Orphan Drug designation, and the trial aims to enroll 11 patients. This is **strong evidence of plausibility** (a complex living tissue implant successfully manufactured and implanted) and also a **maturity milestone**: it required a robust manufacturing and quality platform to meet FDA requirements. 3DBio had to develop processes for cell expansion, bio-ink formulation, a specialized sterile bioprinter, and temporary support structures[17], reflecting how the technology is advancing from lab prototype to a regulated therapeutic product in clinical evaluation.
7. **Dimension Inx’s 3D-printed bone graft (CMFlex™) – first FDA-cleared regenerative graft – Dimension Inx & Desktop Health (press release, 11/2023).** Dimension Inx, a startup, together with Desktop Health, announced that **CMFlex™, a 3D-printed synthetic bone graft, received FDA 510(k) clearance in Dec 2022 and has been used in its first patients**[18][19]. CMFlex is a biofabricated bone scaffold (comprised of hydroxyapatite and PLG polymer) printed with a micro-architecture that promotes bone regeneration. By late 2023 it was successfully implanted in multiple human surgeries (e.g. upper and lower jaw reconstructions and dental socket grafts) as a patient-specific graft that avoids the need to harvest the patient’s own bone[20][21]. Initially available to a few surgeons, it was slated for broader release in 2024[22]. **This is a fully commercial bio-fabricated product in clinical use**, demonstrating that at least niche tissues (bone grafts) have reached Level 6 maturity (regulated product delivered to customers). It provides concrete performance validation – surgeons reported the printed graft’s excellent handling and healing properties[23][24] – and signals that bio-fabrication can produce market-ready medical products.
8. **High cell density and high-resolution 3D bioprinting for vascularized tissues – Shangting You et al. (Sci. Advances, peer-reviewed, 02/2023).** This study tackled a crucial technical challenge: printing tissues that are **both densely cellular and finely detailed** (to support micro-vasculature). The team developed a method to reduce light scattering in a DLP bioprinter by adding iodixanol to bioinks, achieving **50 µm resolution prints at cell densities of 10<sup>8</sup> cells/mL**[25][26]. Using this approach, they fabricated thick, vascular-network-containing tissue constructs that remained **viable in perfusion culture, with embedded endothelial cells forming blood vessel structures after 14 days**[27][28]. This is a **pivotal feasibility result**: it shows that bioprinted tissues can incorporate dense living cells and capillary-scale channels, addressing the previous bottleneck of nutrient supply in larger tissues. Such advances in print fidelity and cell viability increase confidence that functional, larger tissues (with vascular support) can be produced for practical use.
9. **Systemic Bio opens facility for mass-producing bioprinted organ-on-chips – Systemic Bio (wholly-owned by 3D Systems), press release, 04/2023.** Systemic Bio opened a new Houston factory laboratory dedicated to manufacturing its **h-VIOS™ organ-on-a-chip platform** – bioprinted hydrogel scaffolds with human cells for drug testing. The facility includes a

cleanroom for **sterile production of thousands of organ-on-chip devices (plates and chips)**, an unprecedented capacity meant to supply multiple pharma partners in the coming year[29][30]. The h-VIOS system contains vascularized channels to sustain cells and perfuse drugs in a physiologically relevant way[31]. The CEO noted this marks a “**leap from experimental research to full-scale production**”, with automated Print-to-Perfusion technology now manufacturing high-quality tissue models at scale[30][32]. This is strong evidence of maturity on the **biologically-derived product side**: a commercial entity is producing and selling standardized bio-fabricated tissue models in quantity, indicating that reproducibility and scale-up challenges are being met for at least certain applications (drug discovery kits).

10. **Merck KGaA to acquire Hub Organoids (HUB) for organoid technology** – *Merck KGaA (announcement reported via Businesswire/Merck, 12/2024)*. Merck (Darmstadt, Germany) – a major pharma and life-science company – signed an agreement to **acquire Netherlands-based HUB Organoids**, a pioneer in organoid technology[33]. HUB, associated with the Hubrecht Institute, has been a leader in developing patient-derived organoid models (e.g. intestinal organoids). Merck’s acquisition (through its Life Science arm, MilliporeSigma) aims to **advance Merck’s next-generation biology and drug screening portfolio** using organoids. This corporate move underscores the **commercial and strategic value of scalable organoid production**. A top-tier pharma investing tens of millions into organoid capabilities indicates that the technology is viewed as scientifically credible and on the cusp of broader use. It also suggests emerging standards and IP consolidation, which typically occur when a field transitions from academic novelty to an applied biotech toolset.

### 3. Maturity score (1–7) and reasoning

#### A) Final maturity score: 5 (out of 7).

**B) Justification** – *Bio-fabrication technologies* as a whole are **beyond proof-of-concept (Level 4)** and moving into early commercialization, but have not yet achieved broad deployment or competition in end markets (necessary for Level 6 or 7). We have multiple indicators ruling out lower levels: fundamental feasibility is long proven (printing living tissues works in the lab – Level 2/3 achieved years ago), and importantly **functional prototypes have been demonstrated in biologically relevant contexts (Level 4)**. For example, a bioprinted ear implant has been successfully implanted in a human trial, showing real tissue function[15], and a 3D-printed bone graft has FDA clearance and is being used by surgeons, demonstrating **viability as a medical product** rather than just a lab demo (evidence of Level 5–6)[18][19]. Moreover, **well-capitalized actors are involved**: major companies (3D Systems, Merck KGaA, Stratasys, etc.) and consortia (ARMI BioFabUSA) are investing and competing to develop production platforms and scalable processes, which is characteristic of Level 5. The presence of an actual manufacturing facility for organ-on-chip devices and the first wave of commercial products (even if limited release) is a strong Level 5 signal.

However, the field has not yet reached full maturity (Levels 6–7) because **routine, volume production and widespread adoption are only beginning**. The evidence shows *initial* product launches and clinical trials, not a robust pipeline of competing products used at scale. For instance, the bone graft product (CMFlex) is only in limited rollout as of 2024[34], and custom tissue implants like the bioprinted ear are still in early clinical study – not yet broadly available therapies. The integrated “tissue factory” platforms (like ARMI’s Tissue Foundry) are at prototype stage, and many biofabrication successes are one-off or small-batch (e.g. thousands of organoids for testing, or a few patients treated). We **do not yet see**

**multiple companies selling interchangeable tissue products in large quantities** or extensive revenue streams from bio-fabricated tissues, which would mark Level 6 (growing customer demand, scaling production with cost decline). In short, the **trajectory is clearly upward** – substantial recent progress has elevated the score to 5 – but **evidence for Level 6 is still missing**: we need to see manufacturing scaling up with economies of scale and a competitive market of bio-fabricated products being adopted in industry/medicine.

**C) Sub-score breakdown** – This ART comprises several sub-technologies that are maturing at slightly different paces, so an average was used for the bundle score: - **Bioprinted therapeutic tissues (implants and grafts):** *Maturity ~5*. Achieved first human uses and regulatory clearances, indicating PoC and initial commercial viability. *Key evidence*: Dimension Inx's FDA-cleared bone graft used clinically[18][19], 3DBio's implanted ear cartilage in trials[15]. Multiple startups and large firms are in this space (competition forming), but products are just entering the market now, not yet widespread (hence not a 6). - **Automated biofabrication platforms (hardware & processes):** *Maturity ~4*. Demonstrated in pilot settings – e.g. ARMI's modular Tissue Foundry and academic automated bioprinters show that fully automated, closed-loop production is technically feasible[6]. Yet these are still prototypes or bespoke systems; they meet functionality requirements (solving contamination, scalability issues) but are not yet deployed in volume manufacturing or commercialized as turnkey products. Further engineering and cost optimization are ongoing before crossing to Level 5. - **Mass-produced living tissue models (organoids-on-demand for R&D):** *Maturity ~4–5*. Organoid and tissue model production is rapidly scaling with strong industry buy-in. Pharma companies are partnering or acquiring organoid tech (e.g. Merck's HUB acquisition) and new facilities can produce thousands of tissue units for testing[29][30]. This indicates a transition from lab research to **marketable services/products (early Level 5)**. Still, the market is emerging – standards and consistency are being established now, and significant expansion is expected in the next few years rather than already realized.

Taking these together, the **aggregate maturity is about mid-stage (Level 5)**. The more advanced segments (some specific products) pull it above Level 4, while the platform and infrastructure aspects still in development prevent claiming Level 6. In summary, bio-fabrication technologies are at the point where **key proofs have been delivered and first products are launching (score 5)**, with an anticipated jump to Level 6 once scaling and market competition further intensify in the coming years.

## ART 06.042 4D Printed & Programmable Materials

1. **ART extraction**
2. **Primary capability** – Additively manufactured objects that can **change shape or material properties over time** in a programmable way. These “4D printed” structures respond to stimuli (heat, light, moisture, electric/magnetic fields, chemical signals) to alter form or function post-fabrication, essentially acting as “**physical software**” with **on-demand reconfiguration**.
3. **Key sub-components/variants** – (1) **Stimuli-responsive materials** (e.g. shape memory polymers, hydrogels, liquid crystal elastomers, magnetoactive composites) integrated into 3D prints to enable folding, bending, expansion, or stiffness change when triggered. (2) **Multi-material 3D printing techniques** (inkjet, FDM, DIW, vat polymerization) that embed different responsive regions or “memory” into one structure. (3) **Passive vs active control**: some designs rely on inherent material response (e.g. swelling when wet, thermal shape-memory), while others incorporate small embedded actuators or use external fields for coordinated actuation. (4) **Reconfigurable design libraries**: using geometric patterns (origami-inspired folds, lattices, etc.) to achieve complex sequences of shape changes, including one-shot deployments or multi-step transformations. (5) **Application-specific variants**: e.g. self-deploying aerospace components, biomedical implants that change shape in the body, adaptive metamaterials (tunable stiffness, variable porosity), smart textiles that respond to environment, and soft robotic systems without traditional hinges.
4. **Maturity indicators** – Evidence would include **lab prototypes demonstrating repeatable shape-change** and solving prior hurdles (e.g. multi-cycle durability, load-bearing actuation) in real conditions, **field trials or proof-of-concept deployments** (such as a 4D-printed part used in a space mission or in a clinical setting), the emergence of **dedicated equipment or materials** (commercial 4D printers, shape-shifting polymers on the market), **multiple funded programs or consortia** (indicating broad interest and investment), and early **commercial or industrial adoption** (e.g. startups or major manufacturers developing reconfigurable products, or standards efforts for programmable materials). Signs of competition (several companies racing to productize 4D materials) or **performance benchmarks** beating conventional static designs (e.g. significantly improved adaptability or lifecycle cost) would also signal higher maturity.
5. **Evidence (10–20 recent, reliable sources)**
6. **4D Printing Roadmap** – Mahdi Bodaghi et al., Smart Materials and Structures (roadmap review by 44 researchers), **2024**. *<br> A comprehensive 107-page roadmap assembled by experts worldwide highlights the rapid emergence of 4D printing as an “advanced manufacturing technology” distinguished by time-responsive behavior. It surveys recent advancements across biomedicine, aerospace, textiles, electronics, etc., and envisions creating intelligent adaptive objects that dynamically respond to external stimuli*<sup>[1][2]</sup>.

7. **4D Printing for Space Self-Deploying Structures** – Tim Richter & Christina Völlmecke, Applied Sciences (peer-reviewed paper), **12/2023**. <br> *Demonstrates PEEK shape-memory polymer hinges fabricated and “programmed” in a single 4D-printing process for space applications. The hinges achieved ~100% recovery of deformation (fully unfolding) and remained functional across a wide temperature range (including deep-cold), showing viability for self-deploying spacecraft components; however, a high activation temperature is required (~160 °C, a noted challenge for space use)*[\[3\]](#).
8. **4D-Printed Shape-Morphing Orbital Stent (Biomedical)** – Y. Deng et al., **Biomaterials 291**, 121886 (peer-reviewed journal), **2022**. <br> *Produced a CT-visible orbital implant via 4D printing of a shape-memory polyurethane composite to treat enophthalmos (sunken eye). The stent can be inserted in a compact shape and later expand in situ (triggered by body temperature) to fill the orbital cavity. This addresses current implants’ drawbacks – e.g. difficulty achieving precise fill, weak expansion, and large surgical incisions – by enabling a minimally invasive, self-adjusting solution*[\[4\]](#)[\[5\]](#).
9. **One-Piece 4D-Printed Flow Valve (Thermal Activation)** – L. Bottini & A. Boschetto, Progress in Additive Manufacturing (peer-reviewed), **05/2025**. <br> *Describes a rotary diverter valve 3D-printed in a single PLA piece that can open or close without any motor – the valve’s material is “programmed” to deform when heated, thus controlling flow via shape-change. The study optimized FFF printing parameters for maximal shape recovery and fixity. The result is a functional 4D valve that operates using only thermal stimulus (no sensors or electronics), illustrating how 4D printing can simplify mechanisms by embedding actuation in material geometry*[\[6\]](#)[\[7\]](#).
10. **Octopus-Inspired Smart Hydrogel Skin (Halftone-Encoded 4D Printing)** – Haoqing Yang et al. (Hongtao Sun’s group at Penn State), **Nature Communications 16**, 2025 (peer-reviewed; press release by Penn State 02/2026). <br> *Using a custom 4D printing technique, the team created a hydrogel-based “smart skin” that can change color/pattern, texture, and 3D shape on command. Digital instructions (binary halftone patterns) are embedded in the material during printing, allowing it to hide or reveal images and alter stiffness when exposed to triggers like temperature changes, liquids, or mechanical stretch. For example, a hidden image (the Mona Lisa) encoded in the flat hydrogel becomes visible only after specific triggers (cooling or heating)*[\[8\]](#)[\[9\]](#). *This single-material system achieves multiple coordinated responses (camouflage, information display, shape morphing) without layered devices, underscoring the versatility of programmable 4D prints.*
11. **Magnetically Tunable Stiffness Metamaterial (Direct Ink Writing)** – Yoonseok Park et al., Advanced Materials (peer-reviewed), **05/2025**. <br> *Developed a magneto-active mechanical metamaterial capable of a >390% change in stiffness between soft and rigid states*[\[10\]](#). *The team used 4D direct-ink-writing to print a composite of SIS elastomer and neodymium microparticles, creating a lattice that rapidly stiffens or softens under an external magnetic field. They demonstrated multilayer structures and even an adaptive soft robotic wheel that can quickly adjust its stiffness to terrain. This system achieves fast, precise, and reversible tunability of mechanical properties, pointing to applications in soft robotics and prosthetics where on-the-fly material property control is beneficial*[\[11\]](#).
12. **Cycle Durability of 4D-Printed Hinges (Shape Memory PLA)** – J. Huang et al., Materials & Design **260**, 114879 (peer-reviewed, open access), **12/2025**. <br> *Investigated the long-term performance of 4D-printed shape-memory hinges made of PLA via FDM. An optimized hinge design (0.8 mm thickness) showed 99.5% shape recovery on the first use, and an origami-inspired structure using these hinges could fully self-deploy in 8 seconds*[\[12\]](#). *However, under cyclic actuation the hinges’ performance degraded significantly – the shape recovery ratio fell*

to ~25% after 50 heating cycles at 65 °C[13]. This quantifies a key challenge for 4D materials (fatigue and repeatability), emphasizing ongoing needs in material improvements for durability.

13. **BIOMET4D Program – Shape-Shifting Metallic Implants – IMDEA Materials** (EU Horizon Europe Pathfinder project), **Launched 07/2022** – Project Abstract and Updates. <br> A European consortium is developing 4D-printed biodegradable metal implants that change shape in predesigned stages to assist tissue regeneration, then harmlessly degrade. The project targets “shape-morphing metamaterials” and multi-material metal additive manufacturing to create load-bearing implants that can be inserted minimally invasively and then gradually expand (actuate) in the body[14][15]. It aims for a 10× improvement over state-of-the-art, with proof-of-concept in complex applications like craniosynostosis correction (expanding a skull implant as a child grows) and skin tissue expansion. This large-scale R&D effort signals significant investment in bringing 4D materials into real medical use.
14. **Integrated 4D Printing & Programming System (Vendor Example)** – Orion AM “A150” 4D Printer, Orion Additive Mfg. GmbH (technical documentation via Appl. Sci. 2024 paper), **Accessed 2023**. <br> The Orion A150 is a commercial platform that not only 3D-prints shape-memory polymers but also “programs” the printed part’s memory in situ by thermal cycling – all in one machine[16][17]. Researchers used this system to produce and set shape-memory hinges in one go, eliminating the need for separate ovens or DMA equipment. The existence of such specialized 4D printing hardware in industry demonstrates progress toward practical fabrication workflows and supports more consistent, scalable production of programmable materials.
15. **Light-Fueled 4D-Printed Soft Actuators (No Wiring Needed)** – Sean J. D. Lugger et al., Advanced Materials Technologies 8(5), 2201472 (peer-reviewed), **03/2023**. <br> Reported a liquid crystal elastomer (LCE) actuator that is directly 4D-printed by DIW without any slow UV curing step. The printed supramolecular LCE devices show reversible shape-change under light illumination and can bend with enough force to lift a small load[18]. Using an azobenzene additive, the actuators respond to light via both photothermal heating and photochemical motion, and they work in air or under water. This is a clear proof-of-concept of wireless control of a 4D-printed material (using light as the trigger), illustrating feasibility of remotely-controlled shape-morphing components for soft robots or deployable structures.

#### 16. Maturity score (1–7) and reasoning

**A) Final score: 3 (out of 7) – Laboratory Prototype stage.**

**B) Justification:** The evidence shows **numerous lab-scale prototypes and experimental demonstrations**, which goes beyond mere theory or single experiments (ruling out Levels 1–2). Researchers have fabricated working 4D materials that solve specific technical challenges – for instance, multi-material prints that achieve complex shape changes and even functional devices like valves and stents, indicating key functionality is achieved (meets Level 3 criteria)[6][4]. These prototypes demonstrate clear *benefits* (e.g. a self-deploying stent that avoids invasive procedures, or a valve with no moving parts) and address prior bottlenecks in principle. **However, the technology is not yet at proof-of-concept for mass production or widespread deployment (Level 4).** There is little evidence that these 4D-printed devices fully meet real-world reliability or cost requirements – in fact, durability and materials limitations are still significant (e.g. 75% performance loss after 50 cycles in a lab hinge test[13]). We also do not see products in customers’ hands or competing commercial offerings; investment is mostly in R&D consortia and academic labs rather than in scaling up manufacturing, which rules out Levels 5–7. In short, 4D programmable materials are **scientifically proven and**

**actively prototyped** (many stimuli and use-cases have working demos), but **remain in the experimental/validation phase**, with substantial engineering work needed to reach commercial viability. Evidence of ongoing challenges (high actuation temperatures, material fatigue, regulatory hurdles for new materials, etc.) shows that a fully functional, market-ready product has not yet been realized – keeping the maturity at *TRL 3*.

**C) Sub-component breakdown:** Different application threads of 4D materials are at similar maturity, mostly in early prototype stage. For example, **4D-printed aerospace/robotic components** (shape-memory hinges, tunable metamaterials) are demonstrated in lab but not field-qualified ( $\approx$  Level 3)[3][10]. **Biomedical 4D implants** have shown feasibility in animals or bench tests (e.g. a self-expanding stent[4]), approaching proof-of-concept but still requiring clinical validation (Level 3 to 4). **Smart textiles and consumer uses** are largely conceptual or at prototype demos in labs (Level 2–3). Because these variants all share the core enabling technology (stimuli-programmable materials) and none have a sustained commercial rollout yet, the **overall maturity is best represented as Level 3** – multiple compelling prototypes exist, attracting broad research investment, but **no fully field-tested, commercially packaged product** has emerged to push it into the next stage.

## ART 06.043 Volumetric Additive Manufacturing

### 1. ART extraction

**A) Primary capability** – The ART promises **3D printing entire objects “all at once” instead of layer-by-layer**. In a single step, shaped light/energy fields cure a photosensitive volume, forming a solid object throughout its interior. This yields **drastically shorter print times (seconds or minutes vs hours)** and produces **complex, smooth parts** (with internal channels, lattices, moving elements) without supports.

**B) Key sub-components/variants** – Volumetric 3D printing spans several approaches:

- **Tomographic projection (Computed Axial Lithography, CAL):** Project a series of 2D images around a rotating resin to reconstruct the 3D dose (essentially reversing a CT scan)[1][2]. Simpler hardware (just a projector, rotating vial) but requires careful dose calibration. Recent improvements include *holographic tomographic* methods using phase-modulating SLMs for higher light efficiency[3].
- **Holographic / multi-angle volumetric exposure:** Use beam-shaping optics or rotating mirrors to **project a 3D light intensity pattern** in the resin without rotating the sample[4][5]. E.g. the **DISH method** rapidly rotates a periscope to deliver 360° projections and achieve uniform high-resolution curing in one shot[5][6].
- **Dual-color photopolymerization (Xolography):** Two intersecting light sources (different wavelengths) with a special photoinitiator allow **volumetric curing in a stationary resin**. A moving light sheet “sensitizes” regions, and a second patterned beam solidifies them where they intersect[7]. This enables volumetric printing in continuous resin flow and can create **material property gradients** (by parallel curing of different chemistries)[8][9].
- **Specialized photopolymer materials: Photoswitchable or dual-wavelength resins** (for Xolography) and **“threshold” resins** that only polymerize upon receiving a cumulative dose (for CAL). Also, **biocompatible hydrogels and composite resins** are being formulated for volumetric use[10][11]. Resin chemistry is tuned for fast, controlled curing and minimal shrinkage.

- **Computation & control:** Inverse algorithms (tomographic reconstruction, hologram optimization) compute the projections needed for a given 3D model[12]. **Real-time monitoring and exposure control** loops are emerging to compensate for resin absorption and ensure uniform curing[13][14]. High-speed projectors or laser modulators (DMDs at kHz rates) synchronize with mechanical motion to “encode” the 3D shape in light[15][16].
- **System integration challenges:** *Optical hardware* (DLP projectors, lasers, rotating mirrors) must maintain alignment at high speed[17][16]. Removing uncured resin from internal cavities often requires *post-processing (solvent wash, centrifuge)*[18][19]. Designs must mitigate heat and polymerization shrinkage, and avoid turbulence in any flowing resin during exposure.

### C) Maturity indicators – Evidence of the ART’s progress would include:

- **Laboratory prototypes achieving key feats:** e.g. **printing cm-scale objects in seconds with fine resolution**, demonstrating parts unattainable by layering (intricate overhangs, embedded moving components). Peer-reviewed demos of stable, high-quality prints confirm scientific feasibility[20][21].
- **Expanding performance envelope:** Breakthrough results solving prior limits – for instance, **improving resolution–speed tradeoff** (maintaining tens-of-micron detail at high volume rates[20]), or **multi-material printing** (varying stiffness or composition within one print[22]).
- **Transition to practical use: Proof-of-concept use cases** in demanding environments (e.g. printing in microgravity[23][24], or bioprinting living cells with high viability[25][26]). **Early adoption by researchers or industry**, such as specialized volumetric bioprinters installed in labs, or prototypes used in field trials.
- **Commercial development activity:** Formation of **startups and industry groups** building volumetric printers, **VC funding rounds, product launches, or beta units shipped**. Competition among companies (across US/EU/Asia) and **collaborative projects (EU Horizon grants, national lab programs)** signal momentum. Availability of **compatible materials (resins, bio-inks) sold for volumetric printers** also indicates ecosystem growth[27][28].
- **Roadmaps and scaling plans:** Evidence that volumetric AM is **scaling beyond one-off demos** – e.g. plans for larger build volumes, automation (continuous resin feed, part handling), cost reduction, and integration into manufacturing lines. **Standardization efforts or benchmarks** comparing volumetric print quality/cost against conventional 3D printing would also reflect maturity.

### 2. Evidence (10–20 recent, reliable sources)

**Volumetric AM state-of-the-art review – Whyte et al. (Additive Manufacturing, Mar 2024):** *Peer-reviewed review.* Summarizes 30 recent VAM papers and notes **VAM can print entire objects in seconds/minutes** and overprint around existing parts. However, it finds **few commercial VAM printers available and a very limited materials palette**, with complex methods and specialized hardware requirements posing barriers to wider adoption[29]. (This underscores that the technique works in labs but is still early in commercialization.)

**“Sub-second volumetric 3D printing by holographic light fields” – Wang et al. (Nature, Feb 2026):** *Peer-reviewed journal article.* Demonstrates a new **DISH** method achieving **19 µm**

**feature resolution over a 1 cm volume**, printing millimeter-scale objects in **only 0.6 s**[30]. By rapidly rotating optics (no sample rotation) and optimizing projected holograms, they maintain high resolution and even integrated a flow of resin to **continuously mass-produce complex 3D parts** in a range of liquid acrylate materials[30]. *Significance*: Proves volumetric printing can combine **high precision and ultra-fast speed**, addressing a key previous trade-off and pointing toward scalable production throughput.

**“Holographic tomographic VAM” – Álvarez-Castaño et al. (Nat. Commun., Feb 2025):** *Peer-reviewed journal article (open access)*. Reports a tomographic VAM system using a **holographic phase modulator** for more efficient light delivery. Achieved a **20× improvement in light utilization** vs amplitude-only projection, enabling **millimetric objects with 31 μm details printed in <1 minute with only 40 mW LED power**[21]. Impressively, it printed structures in **scattering media (cell-laden hydrogels, 5×10<sup>5</sup> cells/mL)** with similar speed and resolution[21]. *Significance*: Shows progress in **energy efficiency and bioprinting capability** – volumetric prints can be done with modest light sources and even inside opaque, living materials, expanding practical applications.

**In-space volumetric printing demo – Waddell et al. (Acta Astronautica, Oct 2023):** *Peer-reviewed journal (open access, NASA/academia)*. Describes **“SpaceCAL” experiments on a microgravity flight (May 2022)** using Computed Axial Lithography. Demonstrated that CAL works in microgravity with **fewer distortions** (no sinking in low-viscosity resin) than on Earth[24]. They successfully **printed parts in under 20 s** using a 0.12 Pa·s (120 cP) liquid resin, including geometries **impossible to make on Earth (would deform under gravity)**[31][24]. *Significance*: Validates a functional volumetric printer prototype operating in an operational environment. It suggests **broader robustness** (potential for space-based manufacturing) and solved a major issue (gravity-induced distortion) via the technology’s unique approach.

**Volumetric overprinting around inserts – Bagheri et al. (Scientific Reports, Jan 2026):** *Peer-reviewed journal article (open access)*. Investigates printing **complex shapes around pre-existing solid inserts** using tomographic VAM. Identifies that naive volumetric printing fails with occluding inserts, and introduces an **orientation optimization algorithm** to maximize light exposure from all angles[32]. Using a commercial resin, they successfully **overprinted intricate structures onto complex inserts**, with micro-CT scans confirming improved fidelity and deep feature completion when using the optimized orientations[33]. *Significance*: Demonstrates VAM’s unique ability to **integrate/encapsulate objects in a single print**, and that software improvements can overcome optical challenges. This expands VAM’s applicability in manufacturing hybrid components not feasible by other AM methods.

**VAM for dental devices – Zhang et al. (Additive Manufacturing Frontiers, Jan 2026):** *Peer-reviewed review (open access, CMES China)*. Reviews how VAM could revolutionize dental appliance fabrication. Notes that VAM can **produce oral devices in seconds with superior isotropic strength** and smooth surface[34]. Early studies show **standard dental acrylic resins printed by VAM have far higher fabrication efficiency** than traditional methods, and with tailored photoinitiators plus nano-filler additives, the printed dentures achieved **high mechanical integrity, low shrinkage, and excellent biocompatibility**[35]. *Significance*: Indicates that **industry-specific R&D (dental)** is underway to optimize materials for VAM, aiming for real-world production. It highlights that even legacy materials (acrylics) can be

adapted for volumetric printing to yield **functional, durable parts**, supporting the plausibility of commercial deployment in medtech.

**Automated exposure control for VAM – NRC Canada & U. Victoria (arXiv preprint & news, May 2025):** *Research collaboration (preprint reported in Metrology News).* Developed a **closed-loop optical feedback system** for tomographic VAM[13]. In real time, sensors measure resin curing progress and the system adjusts projector intensity per angle to correct over/under exposure. The result was **feature resolution equal or better than commercial SLA/DLP printers, at up to 10× faster print speeds**[14]. *Significance:* Addresses a critical engineering hurdle – consistency and accuracy across a full 3D volume. This level of **precision and automation (“set-and-forget” printing)**[13] shows that volumetric printers can reach the reliability of today’s high-end 3D printers while preserving speed, paving the way for industrial-grade devices.

**BIO INX & Readily3D volumetric bio-resin (press release, May 2025):** *Vendor technical announcement (BIO INX, BE & Readily3D, CH).* Announced **READYPCL INX**, the first commercial **polyester-based resin optimized for volumetric bioprinting**[27]. Used with Readily3D’s Tomolite printer, it enables printing of **tough, load-bearing tissue constructs (cartilage, bone scaffolds) within seconds to minutes at ~100 µm resolution**[36]. The resin is biocompatible (ISO 10993-5) and fully biodegradable[11]. *Significance:* This shows **active industry ecosystem development** – companies are creating specialized materials for volumetric AM to unlock new applications. The availability of a **ready-to-use volumetric bio-ink** indicates that volumetric printing is moving toward real medical use (e.g. “printing replacement tissues during surgery” is cited as a goal) and that **feedstock limitations are being addressed**.

**Xolo (startup) funding and product development – (3DPrint.com news, Feb 2023):** *Industry news (funding report).* Berlin-based startup **Xolo GmbH** – developer of the “**xolography**” **volumetric printer (Xube)** – raised **€8 million in Series A funding in 2023** to accelerate commercialization[37]. This follows a €2.5 M seed round and the unveiling of their proprietary system that can “**print any design in seconds**” using dual-wavelength volumetric curing[37]. Investors include major tech VCs and a German government-backed deep-tech fund, aiming to help Xolo **bring its volumetric 3D printers from research labs to industrial markets**[38]. *Significance:* Clear evidence of **well-capitalized commercial effort**. Multiple investors are betting on volumetric AM’s potential, and Xolo is one of the first companies turning lab prototypes into a product line. This reflects a **competitive, fast-moving development race** beyond academia, an important marker on the path to widespread adoption.

**Dual-color volumetric printing for tailored mechanics – Bin Wang et al. (Nat. Commun., Jan 2022):** *Peer-reviewed journal article (open access).* Demonstrates **fully 3D control of material stiffness within a print** using dual-wavelength tomographic printing[8]. By mixing acrylate (radical cure) and epoxy (cationic cure) monomers with distinct photoinitiators, they used 455 nm and 365 nm light in one volumetric print to create internal **mechanical property gradients**. Achieved **~300 µm spatial resolution in stiffness tuning and a modulus range of 127–201 MPa** in one object[22]. *Significance:* Extends volumetric AM beyond just geometry – shows **multi-material or functionally graded printing is possible in one step**. This capability could outperform traditional 3D printing in creating parts with spatially optimized properties (for biomechanics, optics, etc.), thereby increasing the technology’s value proposition.

### 3. Maturity score (1–7) and reasoning

#### Overall Maturity Score: 5 (Early commercial prototype stage).

**A) Why not lower:** Volumetric 3D printing has **moved well past theory (Level 1)** – it’s not only experimentally proven[30] but has multiple working prototypes tackling prior roadblocks (e.g. sub-second high-res printing[30], multi-material control[22]). **Lab demos (Level 2–3)** have been plentiful since ~2019, and recent results show key functionality achieved: e.g. printing complex, support-free objects with competitive resolution and mechanics[21][35]. The technology has also **proven viable in new contexts** (bioprinting living cells, microgravity manufacturing), indicating robustness beyond a single lab setup[31][26]. These successes fulfill and exceed Level 3 criteria.

At **Level 4 (proof-of-concept for commercialization)**, we see that volumetric AM **clearly surpasses conventional methods in unique benefits** – it can produce shapes and internal features impossible by layering, and does so dramatically faster[31][26]. Indeed, researchers are citing volumetric printers’ speed and isotropy as game-changers for prototyping and small-batch production[34][26]. Evidence of meeting practical requirements is emerging: e.g. volumetric-printed parts with comparable accuracy to standard 3D prints[14] and improved material properties like higher isotropic strength and low shrinkage in dental resins[35]. These point to functional viability for real-world use, satisfying Level 4.

**B) Why score = 5:** Several independent actors are now pushing toward **productization of volumetric printers**, which is characteristic of Level 5. Notably, **multiple startups in different regions have working volumetric 3D printers** and have secured significant funding (e.g. **Xolo in Germany with €8M Series A**[37], Readily3D in Switzerland selling Tomolite bioprinters). They are effectively in competition to refine prototypes and enter niche markets (biomedical models, research tools). Additionally, **national-level programs and major grants** (e.g. EU’s ENLIGHT project with volumetric bioprinting[39], NASA-funded microgravity tests[24]) underscore that **well-resourced organizations see this as a viable near-term technology**. All this momentum goes beyond a single proof-of-concept – it shows an **ecosystem gearing up to deploy volumetric AM**. The **fast-paced progress** is evident: within the last 2–3 years, resolution improved tenfold, print speeds went from tens of seconds to sub-second[20][21], and the first **commercial materials and beta machines** have appeared[27][37]. These are strong indicators of Level 5 (early commercial prototype race).

**Missing evidence for Level 6:** To reach 6, we’d expect **actual products shipping in volume to customers and scaling of production**. As of now, volumetric printers are **mostly limited to research labs or pilot users** – e.g. Xolo’s and Readily3D’s systems are available but not yet broadly adopted in industry (they target R&D and medical research contexts first). There’s **no indication of dozens of units shipped or any cost reduction from scaling yet** – in fact, the 2024 review highlights that **commercial VAM printers remain scarce and specialized**[29]. Moreover, **materials constraints and process complexities persist**[40], which companies are only beginning to address (with new resins like READYPCl and automated calibration systems in development). This means volumetric AM is **still crossing the gap from lab innovation to reliable product**. Larger industry players (e.g. big 3D printer OEMs) have not yet released competing volumetric machines – competition is growing but not “wide” in the market sense.

**C) Sub-component variation:** All the variants aim at the same goal (rapid layerless printing) and improvements are cumulative, so we treat the **bundle's maturity as a whole**. The most advanced implementations (tomographic and bioprinting volumetric systems) are at ~Level 5, as argued. Some sub-threads:

- *Tomographic VAM (CAL and holographic) – Maturity ~5.* Key sub-systems exist as working prototypes trending toward products: e.g. **Xolo's Xube (tomographic dual-color)** is being marketed to advanced users[37], and volumetric printers are in use for specialized tasks (like microgravity CAL printing[31]). Ongoing improvements in software (exposure correction[14]) and hardware (fast optics[15]) are rapidly closing performance gaps.
- *Volumetric bioprinting – Maturity ~5.* Readily3D's commercial Tomolite printer indicates an available product (targeted to research) and partnerships for materials (BIO INX) show a proto-ecosystem[27][36]. This niche actually has paying customers (labs) and addresses urgent applications (tissue engineering), fueling investment.
- *Advanced research-only variants (e.g. DISH holography, multi-material xolography) – Maturity ~3–4.* These are cutting-edge lab demonstrations (Nature 2026) showing what might be possible next[30]. They solved specific barriers (like speed vs resolution), but are not yet in a deliverable product. However, their existence reinforces that the *core concept is robust and improving*, feeding into the more mature threads above.

Given that **the fundamental capability is shared** across these threads and the **leading groups have already transitioned to early commercial efforts**, the **overall ART is rated at Level 5**. In summary, volumetric additive manufacturing is **on the cusp of commercialization** – proven in principle and prototype, with active commercialization underway – but **not yet a widely adopted, scaled product** (hence not Level 6). The next few years should see it enter select markets, provided materials and engineering challenges continue to be addressed[40].

## Group 7 - Advanced Materials & Nano-engineering

### ART 07.044 Metamaterials for Novel Optics & Connectivity

#### ART extraction

##### Primary capability claimed

- Thin, engineered “metamaterial/metasurface” structures that **shape electromagnetic waves (light and radio)** primarily via micro/nano-scale geometry rather than bulk chemistry, enabling steering, focusing, filtering, absorption, scattering, or polarisation control in compact form factors.
- **Reconfigurability (“programmable surfaces”)** in which the phase/amplitude/polarisation response can be adjusted electronically/software-defined in (near) real time, enabling adaptive beam steering, interference management, and multi-function operation.
- **System-level SWaP advantages** (size/weight/power), plus retrofit potential (tiles/coatings/inserts) that can displace bulk optics/antennas and improve link reliability in obstructed environments.

##### Key variants and sub-threads

- **Flat optics / meta-optics:** metalenses, metaholograms, beam shapers, structural colour, and multi-functional optical metasurfaces.
- **Scalable manufacturing:** wafer-scale / large-area patterning, nanoimprint lithography (NIL), photolithography, hybrid material stacks, and yield/defect tolerance.
- **Tunable optical metasurfaces:** electro-optic, MEMS, phase-change-material (PCM), or resonance-based tuning for dynamic focusing/beam control.
- **Metasurface antennas (RF/mmWave):** low-profile electronically steered antennas and related “wavefront-engineered” apertures.
- **Reconfigurable Intelligent Surfaces (RIS) for wireless:** passive/semi-passive surfaces that redirect signals around blockage, suppress interference, and enable smart radio environments; includes channel modelling, control architectures, and standardisation.
- **Environmental robustness:** thermal stability, outdoor exposure, vibration, and long-term reliability for deployed surfaces (especially RF infrastructure and space/defence contexts).

##### Maturity indicators needed for scoring

- **Peer-reviewed experimental demonstrations** showing high efficiency, large aperture, or broadband operation (optics), and validated beamforming/field trials (RF).
- **Scalable manufacturing proof** (wafer-scale, repeatable replication, high throughput) and evidence of defect tolerance/yield progress.
- **Field trials in realistic environments** (commercial or near-commercial wireless deployments) with measurable coverage/throughput/interference benefits.
- **Standardisation movement** (channel models, evaluation methodology, implementation considerations) from recognised bodies.

- **Commercial delivery evidence** (shipping products or very high-volume deployments), with measurable specifications and compliance/reliability details.

**Evidence (ten to twenty recent, reliable sources)**

**1) Scalable manufacturing of high-index atomic layer–polymer hybrid metasurfaces for metaphotonics in the visible**

**Lead author:** Joohoon Kim et al.

**Venue/type:** *Nature Materials* (peer-reviewed experimental paper)

**Date:** March 2023

**Link:** <https://www.nature.com/articles/s41563-023-01485-5>

**Why it matters:** Demonstrates an explicit **scalable manufacturing route** (hybrid meta-atoms) aimed at overcoming throughput/area barriers that historically blocked mass production of visible metasurfaces, directly addressing manufacturability constraints central to the ART. [1]

**2) 8" wafer-scale, centimetre-sized, high-efficiency metalenses in the ultraviolet**

**Lead author:** Joohoon Kim et al.

**Venue/type:** *Materials Today* (peer-reviewed experimental paper)

**Date:** 2024 (volume/issue date shown; month not stated on the preview page)

**Link:**

<https://www.sciencedirect.com/science/article/abs/pii/S1369702124000105>

**Why it matters:** Reports a route to **centimetre-scale UV metalenses on 8-inch wafers** using reticle patterning + ArF lithography + NIL, with a reported **~80% conversion efficiency at 325 nm**—strong evidence that “flat optics” can move beyond small e-beam prototypes into scalable semiconductor-style flows. [2]

**3) Tantalum pentoxide: a new material platform for high-performance dielectric metasurface optics in the ultraviolet and visible region**

**Lead author:** Cheng Zhang et al.

**Venue/type:** *Light: Science & Applications* (peer-reviewed experimental paper; open via PMC)

**Date:** 2024 (month not clearly surfaced in the excerpted view)

**Link:** <https://pmc.ncbi.nlm.nih.gov/articles/PMC10800353/>

**Why it matters:** Presents Ta<sub>2</sub>O<sub>5</sub> as a **fabrication-friendly wide-bandgap platform** (high refractive index, low loss, large-area deposition) and demonstrates multiple metasurface functions with **reported efficiencies up to ~80%**, supporting feasibility for robust UV/visible meta-optics. [3]

**4) Integrated metasurfaces for re-envisioning a near-future disruptive optical platform**

**Lead author:** Younghwan Yang et al.

**Venue/type:** *Light: Science & Applications* (peer-reviewed review article, but grounded in implementation/manufacturing considerations)

**Date:** June 2023

**Link:** <https://www.nature.com/articles/s41377-023-01169-4>

**Why it matters:** Synthesises the state of **integrated / system-level metasurface adoption**, explicitly linking meta-optics performance to packaging, integration, and manufacturability—helpful for judging practical plausibility and integration readiness beyond isolated device demos. [4]

### 5) 3D-printed multilayer structures for high-numerical aperture achromatic metalenses

**Lead author:** Cheng-Feng Pan et al.

**Venue/type:** *Science Advances* (peer-reviewed experimental paper; open via PMC)

**Date:** December 2023

**Link:** <https://pmc.ncbi.nlm.nih.gov/articles/PMC10732525/>

**Why it matters:** Demonstrates a **fabricated multilayer achromatic metalens** approach (tackling bandwidth/aberration trade-offs) and reports **measured efficiencies up to ~42%** for visible-range devices—evidence of progress on the ART's bandwidth/optical-performance constraints. [5]

### 6) Three-dimensional, multi-wavelength beam formation with integrated metasurface optics for Sr laser cooling

**Organisation/lead:** National Institute of Standards and Technology[6] (with academic/industry co-authors)

**Venue/type:** *Optics Letters* (peer-reviewed experimental paper; PDF)

**Date:** October 2024 (published 17 Oct 2024; letter dated 1 Nov 2024)

**Link:** <https://tf.nist.gov/general/pdf/3273.pdf>

**Why it matters:** Shows metasurfaces integrated into a demanding precision-physics context, with **multi-wavelength beam pointing/divergence/polarisation control** across multiple mm-scale metasurfaces on a single substrate—strong evidence of system integration plausibility (alignment reduction, compactness). [7]

### 7) Roadmap for Optical Metasurfaces

**Lead author:** Arseniy I. Kuznetsov et al.

**Venue/type:** *ACS Photonics* (peer-reviewed roadmap/review)

**Date:** February 2024 (PubMed lists 27 Feb 2024; issue later in 2024)

**Link:** <https://pubmed.ncbi.nlm.nih.gov/38550347/>

**Why it matters:** A high-authority metasurface roadmap that explicitly outlines **remaining engineering bottlenecks** (e.g., scale, efficiency/bandwidth trade-offs, integration) and near-to-mid-term R&D directions, supporting maturity assessment across the full optical stack. [8]

### 8) Highly efficient, tunable, electro-optic metasurfaces based on quasi-bound states in the continuum (*preprint*)

**Lead author:** Christopher Damgaard-Carstensen et al.

**Venue/type:** arXiv (preprint with experimental metrics stated)

**Date:** December 2024

**Link:** <https://arxiv.org/abs/2412.01449>

**Why it matters:** Reports an electro-optic metasurface achieving **~95% modulation depth at telecom wavelengths** (with stated electrical bandwidth and voltage conditions), evidencing credible pathways to **software-defined/tunable optical surfaces**, while also signalling that this sub-thread is still pre-product. [9]

### 9) Continuous Varifocal Metalens Based on Phase-Change Material (*preprint*)

**Lead author:** Yilong Cui et al.

**Venue/type:** arXiv (preprint)

**Date:** December 2024

**Link:** <https://arxiv.org/abs/2412.07257>

**Why it matters:** Demonstrates a continuously tunable (PCM-based) metalens reporting **focal length tuning (tens of  $\mu\text{m}$ ) while maintaining >75% focusing efficiency**, directly relevant to

the ART's claim of dynamically reconfigurable flat optics (with remaining questions on cycling, packaging, and high-volume manufacturability). [10]

#### 10) STMicroelectronics and Metalenz sign a new licence agreement to accelerate metasurface optics adoption

**Organisations:** STMicroelectronics[11] and Metalenz[12]

**Venue/type:** Industry press release (shipment/manufacturing claim; treat as commercial evidence)

**Date:** July 2025

**Link:** <https://newsroom.st.com/media-center/press-item.html/t4717.html>

**Why it matters:** States that, **since 2022**, ST has shipped “**well over 140 million**” **metasurface optics and related modules** and is leveraging a **300 mm semiconductor + optics manufacturing platform**—strong evidence of real scaling, qualification, and high-volume delivery in at least one major application class (3D sensing modules). [13]

#### 11) HAWK u8 GEO / GEO-LTE product sheet (*vendor technical doc*)

**Vendor:** Kymeta[14]

**Venue/type:** Product datasheet (measurable RF performance and compliance)

**Date:** Specifications as of May 2022 (rev D)

**Link:** <https://www.idirect.net/wp-content/uploads/2023/01/ProductSheet-Kymeta-Hawk-u8.pdf>

**Why it matters:** Provides concrete commercially packaged performance for a low-profile electronically steered terminal (e.g., scan range, Ku-band RX/TX bands, **EIRP ~46 dBW, G/T up to ~12 dB/K**, IP rating, operating temperatures, regulatory compliance), indicating metamaterial/metasurface-derived apertures have reached deliverable hardware in connectivity markets. [15]

#### 12) EchoShield® technical spec sheet (*vendor technical doc*)

**Vendor:** Echodyne[16]

**Venue/type:** Product specification sheet

**Date:** 2025 (copyright shown on document)

**Link:** [https://www.echodyne.com/media/12tbkrho/ts-echoshield-echodyne\\_5jl1.pdf](https://www.echodyne.com/media/12tbkrho/ts-echoshield-echodyne_5jl1.pdf)

**Why it matters:** Documents a fielded “cognitive metamaterials ESA (MESA)” radar with measurable metrics (e.g., **Ku-band 15.4–16.6 GHz, <0.5° angular track accuracy, 10 Hz update rate, >1,000 tracks**, environmental specs), supporting maturity of metamaterial-based RF wave-control apertures in real products. [17]

#### 13) ETSI GR RIS 003 V1.1.1: Communication models, channel models, channel estimation and evaluation methodology

**Organisation:** European Telecommunications Standards Institute[18]

**Venue/type:** Standards-body technical report / methodology baseline

**Date:** June 2023

**Link:**

[https://www.etsi.org/deliver/etsi\\_gr/RIS/001\\_099/003/01.01.01\\_60/gr\\_RIS003v010101p.pdf](https://www.etsi.org/deliver/etsi_gr/RIS/001_099/003/01.01.01_60/gr_RIS003v010101p.pdf)

**Why it matters:** Establishes a recognised standardisation artefact for RIS evaluation, including scope covering **trade-offs between EM accuracy and simplicity**, channel modelling, and **channel estimation overhead challenges for large-element surfaces**—

critical maturity evidence for “programmable RF surfaces” moving toward interoperable ecosystem definitions. [19]

#### 14) ETSI GR RIS 004 V1.1.1: Implementation and practical considerations

**Organisation:** ETSI

**Venue/type:** Standards-body implementation report

**Date:** March 2025

**Link:**

[https://www.etsi.org/deliver/etsi\\_gr/RIS/001\\_099/004/01.01.01\\_60/gr\\_ris004v010101p.pdf](https://www.etsi.org/deliver/etsi_gr/RIS/001_099/004/01.01.01_60/gr_ris004v010101p.pdf)

**Why it matters:** Focuses explicitly on **implementation-level** considerations (hardware/control, deployment practicality), signalling movement from purely theoretical literature toward engineering constraints, test methods, and deployability requirements. [20]

#### 15) ETSI GR RIS 006 V1.1.1: Multi-functional RIS—modelling, optimisation, and operation

**Organisation:** ETSI

**Venue/type:** Standards-body report (multi-function operation, deployment)

**Date:** June 2025

**Link:**

[https://www.etsi.org/deliver/etsi\\_gr/RIS/001\\_099/006/01.01.01\\_60/gr\\_ris006v010101p.pdf](https://www.etsi.org/deliver/etsi_gr/RIS/001_099/006/01.01.01_60/gr_ris006v010101p.pdf)

**Why it matters:** Treats RIS as more than a reflector—covering **multi-functional surfaces** (e.g., transmission/reflection combinations and other functions), and suggests operational/deployment pathways, aligning with the ART’s “software-defined wave-control surface” vision while also evidencing that standards discussions are still consolidating. [21]

#### 16) A filtering reconfigurable intelligent surface for interference-free wireless communications

**Lead author:** Jing Cheng Liang et al.

**Venue/type:** *Nature Communications* (peer-reviewed experimental paper; open)

**Date:** May 2024

**Link:** <https://www.nature.com/articles/s41467-024-47865-6>

**Why it matters:** Demonstrates a RIS with **frequency-selective behaviour** plus **2-bit phase shifting**, directly supporting the ART’s claim that engineered surfaces can combine filtering + steering to mitigate interference in crowded spectral environments. [22]

#### 17) Field trial measurement and channel modeling for reconfigurable intelligent surface

**Lead author:** Peng Zheng et al.

**Venue/type:** *Digital Communications and Networks* (peer-reviewed experimental paper; open access)

**Date:** June 2023

**Link:** <https://www.sciencedirect.com/science/article/pii/S2352864822002103>

**Why it matters:** Explicitly reports **outdoor and indoor field trials** for a sub-6 GHz, 1-bit RIS and develops/validates pathloss and radiation-pattern modelling against measurements—key plausibility evidence that RIS effects persist outside lab chambers and can be modelled for network planning. [23]

#### 18) Design and validation of scalable reconfigurable intelligent surfaces

**Lead author:** Marco Rossanese et al.

**Venue/type:** *Computer Networks* (peer-reviewed paper with prototyping + data release)

**Date:** March 2024

**Link:**

<https://www.sciencedirect.com/science/article/abs/pii/S1389128624000409>

**Why it matters:** Describes and empirically characterises an RF-switch/PCB-based RIS architecture designed for **scalability and reproducible experimentation**, including modular construction and public dataset release—useful maturity evidence for practical prototyping and benchmarking at scale. [24]

#### 19) **Prototyping and real-world field trials of RIS-aided wireless communications** *(preprint)*

**Lead author:** Xilong Pei et al.

**Venue/type:** arXiv (preprint; includes field measurements)

**Date:** August 2023

**Link:** <https://arxiv.org/abs/2308.03263>

**Why it matters:** Reports multiple experimental settings including outdoor tests (reporting **>35 dB received power gain**) and a commercial-network context where gains were smaller (**~4–7 dB**), giving grounded evidence of both upside and practical limits (antenna directivity, environment dependence). [25]

#### 20) **RIS-Aided mmWave O-RAN: coverage extension and user mobility handling** *(preprint)*

**Lead author:** Tawfik Osman et al.

**Venue/type:** arXiv (preprint; system testbed + field trials)

**Date:** October 2025

**Link:** <https://arxiv.org/abs/2510.20088>

**Why it matters:** Presents an implemented **1,024-element (32×32) 1-bit RIS at 28 GHz** integrated with an O-RAN control interface and reports **field-trial received-power gains** (reported ranges for indoor/outdoor trials), directly indicating progress toward practical control-plane integration for deployable RIS. [26]

#### **Maturity score and reasoning**

**Final maturity score: 6**

This ART is already beyond laboratory proof and early PoCs because there is clear evidence of **commercial delivery of metamaterial/metasurface-based wave-control hardware** at scale in at least one major market segment: STMicroelectronics[11] reports shipping **well over 140 million** metasurface optics and related modules since 2022 and highlights a 300 mm manufacturing/qualification platform for metasurface optics. [13] In RF connectivity and sensing, vendor technical specifications show delivered products with measurable performance and regulatory/environmental integration details—e.g., the Kymeta[14] flat-panel electronically steered terminal datasheet provides bands, EIRP/G/T, temperature range and compliance, consistent with a productised metasurface-style aperture. [15] Echodyne[16] similarly publishes a “cognitive metamaterials ESA” radar spec sheet with track accuracy, update rate, and environmental specs, indicating mature product packaging around metamaterial apertures. [17]

At the same time, parts of the ART—especially **network-integrated RIS as infrastructure** and **fast, high-efficiency tunable optical metasurfaces**—remain earlier-stage. Field trials and prototypes exist (including outdoor and commercial-network experiments and O-RAN-

integrated mmWave demonstrations), but these sources still read as **pre-standard / pre-mass-deployment engineering** rather than widely deployed infrastructure. [27] The presence of multiple recent standards-body reports from the European Telecommunications Standards Institute [18] illustrates momentum toward common evaluation and implementation frameworks, but also implies that large-scale interoperability and deployment norms are still being defined. [28]

### Evidence-to-rubric mapping

**What rules out levels 1–5 (why the ART is at least 6): - Delivered products with quantified specifications** exist for metamaterial/metasurface RF apertures (e.g., electronically steered terminals and metamaterials ESA radar), consistent with “products delivered to customers” rather than lab-only prototypes. [29]

- **Very high-volume shipments** are explicitly claimed for metasurface optics modules (hundreds of millions scale is not implied, but “well over 140 million” is explicitly stated), indicating mass manufacturing, qualification, and customer delivery at scale. [13]

- Multiple peer-reviewed papers demonstrate **manufacturing-scalable processes** and large-area/wafer-scale approaches, reinforcing that the underlying engineering is not confined to small, fragile demonstrations. [30]

**What is missing to justify level 7 (why the ART is not 7 overall):** - The evidence set does not cleanly establish that **multiple competing vendors** are delivering comparable metasurface-based products at high volume *across the full ART scope* (optics + connectivity infrastructure) with clearly rising demand; we have strong evidence for one large-scale optics channel and multiple niche-to-established RF products, but not broad cross-market competitive scaling data. [31]

- For RIS-as-network-infrastructure specifically, the evidence remains dominated by **field trials, prototypes, modelling reports, and standards groundwork** rather than ubiquitous deployments with sustained procurement signals. [32]

### Subcomponent breakdown and aggregation

- **Meta-optics in consumer-grade sensing modules** → 6–7 (delivered at very large volumes; manufacturing/qualification highlighted). Key evidence: shipment statement and manufacturing platform positioning. [13]
- **Scalable optical metasurface manufacturing (wafer/large-area)** → 5–6 (credible scalable processes in peer-reviewed work; supports manufacturability). Key evidence: scalable manufacturing in *Nature Materials* and wafer-scale UV metalenses. [33]
- **Tunable optical metasurfaces (electro-optic / PCM metalenses)** → 3–4 (prototype-level, largely preprint evidence; strong plausibility but not yet product scaling). Key evidence: tunable electro-optic modulation and PCM varifocal demonstrations. [34]
- **Metasurface/metamaterial RF apertures (satcom terminals, radars)** → 6 (vendor-published specs and productisation signals). Key evidence: product spec sheets. [35]
- **RIS for cellular / O-RAN integration and deployments** → 4–5 (field trials, measurement-based models, and standards body implementation reports; still not broadly deployed). Key evidence: field trial measurements and O-RAN RIS testbed field trials; ETSI implementation reports. [36]

**Aggregation logic:** Because the ART spans multiple application areas with meaningfully different maturity (mass-produced meta-optics and commercial RF apertures versus earlier-stage RIS infrastructure and tunable meta-optics), an average-based score is appropriate. The existence of high-volume delivered products and well-specified commercial hardware pulls the overall maturity into **level 6**, while the still-developing RIS infrastructure and tunable optical surfaces prevent a level 7 classification. [37]

## ART 07.045 Room-Temperature Superconductors

### 1. ART extraction

#### A) Primary capability claimed (what “room-temperature superconductors” would do)

- Achieve *effectively zero electrical resistance* for bulk current flow at (or near) everyday temperatures, ideally also at *near-ambient pressure* and in *useful magnetic fields* (so it can replace copper/aluminium conductors without cryogenics).
- Provide *practical conductor form factors* (wire/tape/thin film/laminates) with robust encapsulation, joining, monitoring, and predictable behaviour under strain and field.

#### B) Key sub-components / variants implied by the ART description

- **Material families aiming at high  $T_c$ :** hydrogen-rich hydrides/superhydrides (currently high-pressure), “chemically precompressed” ternary hydrides, and other engineered compounds targeting ambient pressure stability.
- **Pressure/temperature stabilisation pathways:** chemical substitution (e.g., ternary alloying), metastable phase retention, and defect/stoichiometry control.
- **Conductor architectures:** superconducting layer + stabiliser metals + outer jacket; cable assemblies (stacked tapes, CORC®, CICC).
- **Joining & interfaces:** low-resistance splices/connectors that do not create weak points;

quality assurance along length.

- **Quench / instability sensing & protection:** monitoring electronics, current diversion strategies, and mechanical design to avoid degradation.
- **Manufacturing controls:** purity, grain alignment/texture, defect control, reproducible composition/phase, and scalable deposition or bulk synthesis.

### C) Maturity indicators that would constitute strong evidence (for this ART specifically)

- **Reproducible, independently verified superconductivity at  $\geq \sim 290\text{--}300\text{ K}$  with clear Meissner/flux exclusion and transport zero resistance, at  $\leq \sim 1\text{ bar}$  (or at least  $\leq \sim$  a few GPa as an interim step), plus meaningful critical current density  $J_c$  and upper critical field  $H_{c2}$ .**
- **Stability under realistic conditions:** survives thermal cycling, humidity/oxidation exposure, mechanical strain/bending, and magnetic-field cycling without catastrophic degradation.
- **Scalable materials processing:** repeatable synthesis and *process windows* demonstrated beyond single short samples (batch repeatability, yield statistics).
- **Conductor-length demonstrations:** continuous lengths (metres  $\rightarrow$  kilometres) with standardised connectors/joints, tested under load.
- **Field trials / system demos:** integration into power devices (cables, transformers, motors), magnets, or thermal-management-limited electronics without cryogenics.
- **Multiple well-capitalised actors and supply-chain evidence:** procurement specs, pilot lines, and a standardisation or qualification ecosystem.

## 2. Evidence (10–20 recent, reliable sources)

### 1) Retraction Note: Room-temperature superconductivity in a carbonaceous sulfur hydride

- **Authors/Org:** Elliot Snider[1] et al.
- **Venue/type:** Nature[2] (retraction note; peer-reviewed journal record)
- **Publication date:** Sept 2022 (published 26 Sept 2022)
- **Link:** <https://www.nature.com/articles/s41586-022-05294-9>
- **Why it matters:** A headline “room-temperature” superconductivity claim (2020) was formally retracted due to unresolved questions about data processing/analysis, underscoring that *extraordinary  $T_c$  claims remain fragile unless independently reproducible with transparent data.* [3]

### 2) RETRACTED ARTICLE: Evidence of near-ambient superconductivity in a N-doped lutetium hydride

- **Authors/Org:** Nathan Dasenbrock-Gammon[4] et al.
- **Venue/type:** Nature (peer-reviewed paper; later retracted)
- **Publication date:** Mar 2023 (published 08 Mar 2023; retracted 07 Nov 2023)
- **Link:** <https://www.nature.com/articles/s41586-023-05742-0>
- **Why it matters:** This paper claimed superconductivity around room temperature ( $\sim 294\text{ K}$ ) at “near-ambient” pressures ( $\sim 1\text{ GPa}$ -scale), but the article was later retracted—highlighting how *near-ambient/ambient RT superconductivity is not yet a stable, validated result.* [5]

### 3) Absence of near-ambient superconductivity in $\text{LuH}_{2\pm x}\text{Ny}$

- **Authors/Org:** Xue Ming[6] et al.
- **Venue/type:** Nature (peer-reviewed experimental replication)
- **Publication date:** May 2023 (published 11 May 2023)
- **Link:** <https://www.nature.com/articles/s41586-023-06162-w>

- **Why it matters:** Replication efforts synthesised nitrogen-doped lutetium hydride and reported *no superconductivity* (down to 2 K) across tested pressures up to ~40 GPa, weighing strongly against near-ambient validity and illustrating the field's *reproducibility gate* for maturity. [7]

#### 4) Observation of non-superconducting phase changes in nitrogen doped lutetium hydrides

- **Authors/Org:** Xiangzhuo Xing[8] et al.

- **Venue/type:** Nature Communications[9] (peer-reviewed experimental study)

- **Publication date:** Sept 2023 (published 26 Sept 2023)

- **Link:** <https://www.nature.com/articles/s41467-023-41777-7>

- **Why it matters:** Reports *no superconducting transition* from ~1.8–300 K and 0–38 GPa, and argues that observed resistance anomalies/colour changes can arise from non-superconducting electronic/structural effects—directly addressing a key failure mode in “RT superconductor” claims: misinterpreting anomalies as superconductivity. [10]

#### 5) Superconductivity above 200 K discovered in superhydrides of calcium

- **Authors/Org:** Zhiwen Li[11] et al.

- **Venue/type:** Nature Communications (peer-reviewed experimental paper)

- **Publication date:** May 2022 (published 23 May 2022)

- **Link:** <https://www.nature.com/articles/s41467-022-30454-w>

- **Why it matters:** Demonstrates *very high critical temperature* superconductivity (reported  $T_c$  ~210 K) in calcium superhydrides synthesised under extreme pressures (~160–190 GPa) and high-temperature laser heating, with reported high inferred field scales (e.g., very large  $H_c$  estimates). This supports *plausibility* for high- $T_c$  via hydrides, but also shows the *practicality bottleneck* (megabar pressures). [12]

#### 6) Enhancement of superconducting properties in the La–Ce–H system at moderate pressures

- **Authors/Org:** Wuhao Chen[13] et al.

- **Venue/type:** Nature Communications (peer-reviewed experimental paper)

- **Publication date:** May 2023 (published 09 May 2023)

- **Link:** <https://www.nature.com/articles/s41467-023-38254-6>

- **Why it matters:** Shows an experimental route to *engineer ternary hydrides* with lower stabilisation pressures than benchmark binary hydrides: synthesising hcp-(La,Ce)H<sub>9–10</sub> (~113 GPa) and reporting superconductivity at ~176 K around ~100 GPa plus very large extrapolated  $H_{c2}$  values. This supports the “chemical tuning” path while still far from ambient pressure. [14]

#### 7) Stoichiometric Ternary Superhydride LaBeH<sub>8</sub> as a New Template for High-Temperature Superconductivity at 110 K under 80 GPa

- **Authors/Org:** Yinggang Song[15] et al.

- **Venue/type:** Physical Review Letters (peer-reviewed experimental paper; indexed record)

- **Publication date:** Jun 2023 (PubMed: 30 Jun 2023)

- **Link:** <https://pubmed.ncbi.nlm.nih.gov/37450815/>

- **Why it matters:** Reports synthesis of a *stoichiometric ternary hydride with resolved structure* and superconductivity up to ~110 K at ~80 GPa, evidencing progress toward lower-pressure high- $T_c$  hydrides. Still, 80 GPa is orders of magnitude above device-relevant pressures. [16]

### 8) Mechanism of high-temperature superconductivity in compressed H<sub>2</sub>-molecular-type hydride CaH<sub>14</sub>

- **Authors/Org:** Zhao Liu[17] et al.
- **Venue/type:** Science Advances (peer-reviewed; open full text via PubMed Central)
- **Publication date:** Mar 2025 (PMC collection date 28 Mar 2025; accepted Feb 2025)
- **Link:** <https://pmc.ncbi.nlm.nih.gov/articles/PMC11952093/>
- **Why it matters:** Reports a hydride with an unusual electronic mechanism discussion and a reported  $T_c$  around ~204 K at very high pressure, while also discussing behaviour at reduced pressures (tens of GPa). It reinforces plausibility that new hydride structural motifs can sustain high  $T_c$ , but remains fundamentally constrained by extreme-pressure synthesis. [18]

### 9) X-ray-diffraction and electrical-transport imaging of superconducting superhydride (La,Y)H<sub>10</sub>

- **Authors/Org:** Abdul Haseeb Manayil Marathamkottil[19] et al.
- **Venue/type:** Nature Communications (peer-reviewed experimental paper)
- **Publication date:** Dec 2025 (published 18 Dec 2025)
- **Link:** <https://www.nature.com/articles/s41467-025-66262-1>
- **Why it matters:** Uses spatially resolved XRD imaging + transport to correlate *local structure domains* with distinct superconducting transitions (onsets reported near ~244 K and ~220 K) in (La,Y)H<sub>10</sub> at megabar pressures, illustrating increasing experimental sophistication and reproducibility work—important for plausibility, but still far from scalable ambient conditions. [20]

### 10) The maximum $T_c$ of conventional superconductors at ambient pressure

- **Authors/Org:** Kun Gao[21] et al.
- **Venue/type:** Nature Communications (peer-reviewed computational/meta-analysis)
- **Publication date:** Sept 2025 (published 10 Sept 2025)
- **Link:** <https://www.nature.com/articles/s41467-025-63702-w>
- **Why it matters:** Analyses large electron-phonon datasets and argues that *room-temperature conventional superconductivity at ambient pressure is extremely unlikely* due to trade-offs between phonon frequency scales and coupling/instability constraints; this is directly relevant to plausibility expectations for “ambient RT superconductors” in phonon-mediated regimes. [22]

### 11) Prediction of ambient pressure conventional superconductivity above 80 K in hydride compounds

- **Authors/Org:** Antonio Sanna[23] et al.
- **Venue/type:** npj Computational Materials (peer-reviewed computational prediction)
- **Publication date:** Feb 2024 (published 28 Feb 2024)
- **Link:** <https://www.nature.com/articles/s41524-024-01214-9>
- **Why it matters:** Uses ML-accelerated screening to propose Mg<sub>2</sub>XH<sub>6</sub> (X = Rh/Ir/Pd/Pt) hydrides with predicted  $T_c$  ranges ~45–80 K (and potentially >100 K with electron doping) at *room pressure*. This is a credible “design-for-ambient-pressure” direction, but remains at the *prediction stage*. [24]

### 12) Feasible route to high-temperature ambient-pressure hydride superconductivity

- **Authors/Org:** Kapildeb Dolui[25] et al.
- **Venue/type:** arXiv preprint (explicitly labelled); page notes a later journal reference in Physical Review Letters

- **Publication date:** Oct 2023 (submitted 11 Oct 2023; revised Apr 2024)
- **Link:** <https://arxiv.org/abs/2310.07562>
- **Why it matters:** Proposes a specific metastable hydride (e.g.,  $\text{Mg}_2\text{IrH}_6$ ) with very high predicted  $T_c$  at ambient pressure and discusses a plausible synthesis route via a related high-pressure-stable precursor phase. This informs plausibility pathways while still lacking experimental synthesis/validation at ambient pressure. [26]

### 13) Absence of Superconductivity in LK-99 at Ambient Conditions

- **Authors/Org:** K. Kumar[27] et al.
- **Venue/type:** ACS Omega (peer-reviewed experimental; open full text via PubMed Central)
- **Publication date:** Oct 2023 (ACS Omega issue: 25 Oct 2023)
- **Link:** <https://pmc.ncbi.nlm.nih.gov/articles/PMC10633996/>
- **Why it matters:** Reports synthesised “LK-99” (Cu-doped lead apatite) samples that are highly resistive (insulator-like) in the measured temperature range and do not show superconductivity signatures, providing a peer-reviewed negative result for a widely publicised ambient-condition claim and emphasising the *gap between viral claims and validated maturity*. [28]

### 14) Technical Specification: REBCO Coated Conductor for the Muon Collider Solenoids Development

- **Authors/Org:** CERN[29] (technical specification / procurement-style requirements)
- **Venue/type:** Institutional technical specification (system/engineering evidence)
- **Publication date:** May 2023
- **Link:** <https://indico.cern.ch/event/1240046/contributions/5356502/attachments/2645865/4579815/HTS%20techspecs%20v3.pdf>
- **Why it matters:** While not room-temperature, it concretely documents how superconductors become “real conductors”: kilometre-scale quantities, defined tape geometry, minimum critical current targets (e.g., at 4.2 K and high fields), unit-length expectations, bend-radius constraints, and acceptance testing—all directly relevant to the ART’s claimed mature-state conductor packaging and QA needs once an ambient-temperature material exists. [30]

### 15) Twisting & Bending Performance of a Subscale CORC® Cable-in-Conduit-Conductor for Fusion and Detector Magnet Applications

- **Authors/Org:** Michael Naus[31] et al.
- **Venue/type:** IEEE Transactions on Applied Superconductivity (peer-reviewed engineering paper; PDF hosted by Advanced Conductor Technologies — treat as vendor-hosted copy of a journal paper)
- **Publication date:** Aug 2025 (journal issue shown as Aug 2025; paper metadata in PDF shows publication workflow in late 2024/early 2025)
- **Link:** <https://www.advancedconductor.com/wp-content/uploads/2025/11/Naus-M.-IEEE-Trans.-Appl.-Supercond.-35-4800805-2025.pdf>
- **Why it matters:** Demonstrates engineering-maturity elements the ART anticipates (mechanical deformation tolerance, manufacturability issues, measured performance degradation under twisting/bending) for high-temperature superconducting cable architectures—supporting the claim that *if* a room-temperature material existed, there is an

established pathway for conductor/cable qualification; but it also illustrates how sensitive superconducting performance can be to mechanical handling. [32]

### 3. Maturity score (1–7) and reasoning

#### A) Final maturity score: 2

#### B) Justification mapped to the rubric

##### Why the evidence rules out level 1 (purely theoretical / early academic interest)

- Multiple peer-reviewed experimental works in the last four years demonstrate **very high- $T_c$**  superconductivity in hydrogen-rich hydrides/superhydrides (e.g.,  $T_c \sim 210$  K in calcium superhydrides under  $\sim 160$ – $190$  GPa; high- $T_c$  ternary hydride systems engineered by alloying; and additional hydride families explored experimentally). [33]
- The field is not just hypothesising “RT superconductivity”: it is repeatedly demonstrating *near-room-temperature class transition temperatures*—but under extreme pressures and specialised apparatus, indicating an established laboratory operating principle (rubric level 2). [34]

##### Why the ART does *not* reach level 3 (laboratory prototype solving a key blocking problem for deployment)

- The ART’s defining commercialisation blocker is **ambient (or device-compatible) pressure operation** plus usable fields/critical currents in scalable form factors. The strongest “near-ambient” claim in the period (Lu-N-H) was **retracted**, and independent experimental replication papers reported **no superconductivity** across wide conditions. [35]
- The best-validated high- $T_c$  hydrides still require **megabar-class pressures** (hundreds of GPa) achievable in diamond-anvil-cell experiments, which is fundamentally incompatible with wires/tapes/coatings operating in ordinary infrastructure—so the technology is not yet at a “prototype conductor” stage that could plausibly scale. [36]
- Computational work is progressing toward ambient-pressure candidates (ML/high-throughput predictions), but these remain **predictions without experimental synthesis/validation** at ambient pressure, which is insufficient for level 3. [37]

##### What is still missing to justify level 3 (and beyond)

- A **reproducible, independently replicated** demonstration of superconductivity at  $\sim 300$  K at  **$\sim 1$  bar** (or, as an interim, at dramatically reduced pressures that are realistically packageable), with robust Meissner screening and transport zero resistance, plus quantified  $J_c$ ,  $H_{c2}$ , and stability under strain. [38]
- Evidence of **materials/process scalability** (repeatable synthesis beyond small DAC samples; yield/variability statistics; degradation modes; joining methods), and **device-relevant prototypes** (even short, non-cryogenic conductor segments). The present evidence base does not show this for room-temperature materials. [34]

#### C) Sub-score breakdown (because the ART is effectively a bundle) and aggregation

- **High- $T_c$  superconductivity in hydrides under extreme pressure**  $\rightarrow \sim 2$ – $3$  (solid experimental demonstrations exist; however, not deployable)  $\rightarrow$  key sources: calcium superhydrides at  $> 200$  K (megabar pressures); ternary hydrides pushing pressure down but still tens to hundreds of GPa. [36]

- **Near-ambient / ambient-pressure “room-temperature” claims** → ~1 (claims retracted or not reproduced; no stable validated effect) → key sources: retractions and negative replications in Lu-N-H; negative results in LK-99. [39]
- **Ambient-pressure candidate design (computational/ML screening)** → ~1–2 (credible predictions and proposed synthesis routes, but limited experimental confirmation) → key sources:  $\text{Mg}_2\text{XH}_6$  predictions; arXiv high-throughput route paper; ambient-pressure limit analysis. [37]
- **Conductor engineering know-how (for existing cryogenic HTS, not RT materials)** → ~5–6 as a *supporting ecosystem* (procurement specs, cable tests), but **not** the bottleneck material capability → key sources: CERN REBCO tech specification; CORC/CICC deformation testing paper. [40]

**Aggregation to one ART score:** The ART’s core promise is **room-temperature superconductivity in practical form factors without cryogenics**, which is dominated by the *material feasibility at ambient conditions*. Given that verified high- $T_c$  superconductivity exists only under extreme pressures (supporting plausibility), while near-ambient “RT” claims have failed validation and ambient-pressure candidates remain largely predictive, the overall maturity most defensibly aligns with **rubric level 2**. [41]

## ART 07.046 Self-Healing & Smart Polymers

### ART extraction

#### Primary capability the ART claims

- Autonomous repair of polymer parts (and polymer-matrix composites) such that microcracks, punctures, or abrasion damage can be sealed and meaningful mechanical/barrier function restored without disassembly (intrinsic dynamic bonds; extrinsic microcapsules or microvascular delivery).
- Adaptive (“smart”) behaviour in the same material platform, where the polymer network can shift properties such as stiffness/damping/permeability/adhesion/electrical conductivity in response to stimuli (temperature, strain, moisture, light, chemicals), potentially with low-power sensing and calibration.

#### Key sub-components or variants

- Intrinsic self-healing networks: dynamic covalent chemistries (e.g., Diels–Alder, exchangeable bonds/vitrimers) and reversible supramolecular interactions (e.g., hydrogen bonding, metal–ligand coordination, disulfide exchange) enabling repeatable healing.

- Extrinsic self-healing systems: encapsulated healing agents (microcapsules/nanocontainers) and/or microvascular channel networks that release or deliver repair chemistry when damaged.
- Vitrimer-based reprocessable thermosets and composites (including fibre-reinforced) that combine reparability with end-of-life reprocessing/recycling routes.
- Multifunctional self-healing conductors/ionogels/polymer electrolytes for soft electronics and energy devices (restore conductivity/electrochemical interfaces after mechanical damage).
- Smart coatings and films that combine self-healing with adaptive surface/optical/thermal properties (e.g., thermochromism, hydrophobicity) and/or corrosion-inhibitor release.

#### **Maturity indicators that would constitute evidence for this ART**

- Repeatable, quantified healing efficiencies (mechanical strength/toughness recovery; barrier/corrosion protection recovery; conductivity restoration) and multi-cycle performance under realistic damage modes.
- Device-level or component-level demonstrations (e.g., sensors, energy devices, structural composite joints) rather than only “materials coupons.”
- Standardised or pre-standard test methods for “healing efficiency” and durability/ageing (indicating readiness for qualification and procurement).
- Evidence of manufacturability (thermoforming/reprocessing, scalable synthesis, integration with fibres/fillers/conductive networks).
- Commercial shipments in at least some subdomains (e.g., coatings/films) with datasheets and warranty-backed performance claims, signalling real customer deployment.

#### **Evidence (10–20 recent, reliable sources)**

All sources below were published within the strict window **February 2022 to February 2026** (inclusive), and were prioritised toward peer-reviewed experimental papers, authoritative standards/consortia outputs, and vendor technical documentation with measurable properties.

#### **Evidence coverage map**

Collectively, the dossier spans (i) standardisation and test methodology for self-healing composites, (ii) intrinsic self-healing chemistries with quantified recovery, (iii) extrinsic capsule/vascular approaches for coatings and composites, (iv) multifunctional self-healing for electronics/energy devices, (v) commercialised self-healing polymer films/coatings, and (vi) sustainability/circularity constraints and lifecycle considerations. [\[1\]](#)

#### **Annotated sources**

**1) CWA 17896: Test method for determining adhesive properties in joints of continuous fibre-reinforced polymer composites using a Lap Strap specimen (applicable to repairable/self-healing composites)**

**Authors/organisation:** CEN[\[2\]](#) (workshop agreement; includes multiple industrial and research stakeholders)

**Venue/type:** Standards / pre-standard test methodology (CEN Workshop Agreement)

**Publication date:** June 2022

**Link:** [https://www.cenelec.eu/media/CEN-CENELEC/CWAs/RI/cwa17896\\_2022.pdf](https://www.cenelec.eu/media/CEN-CENELEC/CWAs/RI/cwa17896_2022.pdf)

**Why it matters:** Establishes a repeatable method to quantify “knockdown effect” and repair/healing efficiency in composite joints, explicitly covering capsule-based, vascular, intrinsic polymer, and vitrimer technologies—an indicator that the field is moving toward qualification-style evaluation rather than ad-hoc lab tests. [3]

## 2) 3M Paint Protection Film Series 100 Gloss Product Bulletin

**Authors/organisation:** 3M[4]

**Venue/type:** Vendor technical doc (product bulletin / datasheet-style)

**Publication date:** June 2022

**Link:** <https://multimedia.3m.com/mws/media/21497300/3m-paint-protection-film-series-100-gloss-product-bulletin-june-2022.pdf>

**Why it matters:** Demonstrates a commercial self-healing polyurethane film product with specified construction and thickness (e.g., ~7.5 mil / 0.19 mm construction) and a warranty, showing that at least “scratch-healing polymer films” are already beyond PoC and in real customer deployment. [5]

## 3) A self-healing polymerized-ionic-liquid-based polymer electrolyte enables long lifespan and dendrite-free solid-state Li metal batteries at room temperature

**Authors/organisation:** Xiuqing Lin[6] et al.

**Venue/type:** Peer-reviewed paper (journal: Materials Horizons[7])

**Publication date:** First published 19 Dec 2022 (journal issue 2023)

**Link:** <https://pubs.rsc.org/en/content/articlelanding/2023/mh/d2mh01289h>

**Why it matters:** Reports a self-healing polymer electrolyte that can reconstruct dendrite-induced defects at the Li/electrolyte interface; Li|LFP full cells show ~91.2% capacity retention after 206 cycles at room temperature—evidence that “self-healing + functional transport property (ion conduction)” can be integrated into working electrochemical devices. [8]

## 4) Vascular smooth muscle-inspired architecture enables soft yet tough self-healing materials for durable capacitive strain-sensor

**Authors/organisation:** FuYao Sun[9] et al.

**Venue/type:** Peer-reviewed paper (journal: Nature Communications[10])

**Publication date:** 10 Jan 2023

**Link:** <https://www.nature.com/articles/s41467-023-35810-y>

**Why it matters:** Demonstrates a route to overcome the common trade-off between softness/self-healing and fracture toughness, reporting fracture toughness up to ~111 kJ/m<sup>2</sup> and ultra-fast healing (~98% efficiency within ~1 minute under NIR-assisted conditions)—highly relevant to plausibility for durable, damage-tolerant “smart” polymer components. [11]

## 5) Fast self-healing at room temperature in Diels–Alder elastomers

**Authors/organisation:** Eva Roels[12] et al.

**Venue/type:** Peer-reviewed paper (open access journal article via PubMed Central[13])

**Publication date:** Collection date Sep 2023 (received Jul 2023; accepted Aug 2023)

**Link:** <https://pmc.ncbi.nlm.nih.gov/articles/PMC10490179/>

**Why it matters:** Shows macroscopic damage healing at room temperature with complete restoration of mechanical properties within hours and partial recovery within minutes by

tuning stoichiometry—direct evidence that intrinsic reversible covalent networks can support autonomous/low-stimulus healing (a key feasibility claim for everyday polymer parts). [14]

#### 6) Scotchgard Paint Protection Film Pro Series 200 Gloss Product Bulletin

**Authors/organisation:** 3M

**Venue/type:** Vendor technical doc (product bulletin)

**Publication date:** September 2023

**Link:** <https://api-shop.spandex.com/medias/Data-Sheet-3M-Scotchgard-PPF-Pro-Series-200-Gloss-Sep-2023-US.pdf>

**Why it matters:** Reinforces market maturity for at least one self-healing polymer category (urethane films), including a 10-year warranty and performance-focused product positioning; this supports that self-healing is already commercial in surface-protection use cases. [15]

#### 7) Scotchgard Paint Protection Film Pro Series 200 Matte Product Bulletin

**Authors/organisation:** 3M

**Venue/type:** Vendor technical doc (product bulletin)

**Publication date:** November 2023

**Link:** <https://multimedia.3m.com/mws/media/23583950/scotchgard-paint-protection-film-pro-series-200-matte.pdf>

**Why it matters:** Provides another up-to-date commercial spec for self-healing polyurethane films (including film + adhesive thickness and stated “self-healing technology”), supporting that self-healing polymer functionality can survive real-world deployment constraints like installation, weathering, and long warranties. [16]

#### 8) A stable and self-healing thermochromic polymer coating for all-weather thermal regulation

**Authors/organisation:** Yuncong Liu[17] et al.

**Venue/type:** Peer-reviewed paper (journal article; thermochromic “smart coating” integrating adaptive response + self-healing)

**Publication date:** September 2023

**Link:**

[https://www.researchgate.net/publication/373687550\\_A\\_Stable\\_and\\_Self-Healing\\_Thermochromic\\_Polymer\\_Coating\\_for\\_All\\_Weather\\_Thermal\\_Regulation](https://www.researchgate.net/publication/373687550_A_Stable_and_Self-Healing_Thermochromic_Polymer_Coating_for_All_Weather_Thermal_Regulation)

**Why it matters:** Reports a smart coating concept where reversible phase behaviour (thermochromism) is tied to reversible interactions (ion–dipole) that also enable self-healing and environmental stability across harsh conditions—evidence for “adaptive behaviour” coexisting with self-repair in one platform (even if activation may be stimulus-dependent). [18]

#### 9) Dual rapid self-healing and easily recyclable carbon fiber reinforced vitrimer composites

**Authors/organisation:** Mingzhuan Li[19] et al.

**Venue/type:** Peer-reviewed paper (journal: Chemical Engineering Journal[20])

**Publication date:** 15 January 2024

**Link:**

<https://www.sciencedirect.com/science/article/abs/pii/S1385894723068791>

**Why it matters:** Reports >95% scratch recovery in ~5 minutes for the vitrimer resin and ~77.4% interfacial healing retained after five cycles in carbon fibre/vitrimer composites, plus chemical recycling that recovers both resin and carbon fibre—strong evidence that self-

healing can be engineered into high-performance composites with multi-cycle capability and circularity pathways. [21]

#### 10) Sustainability of self-healing polymers: A holistic perspective towards circularity in polymer networks

**Authors/organisation:** Kenneth Cerdan[22] et al.

**Venue/type:** Peer-reviewed review/roadmap-style synthesis (journal: Progress in Polymer Science[23])

**Publication date:** Available online 26 March 2024 (issue dated May 2024)

**Link:**

[https://cris.vub.be/ws/portalfiles/portal/121165360/1\\_s2.0\\_S0079670024000339\\_main.pdf](https://cris.vub.be/ws/portalfiles/portal/121165360/1_s2.0_S0079670024000339_main.pdf)

**Why it matters:** Provides lifecycle-anchored analysis of intrinsic vs extrinsic self-healing chemistries, explicitly linking healing efficiency, number of healing cycles, processing, and end-of-life options (reprocessing/recycling/biodegradation) to overall sustainability—directly relevant to feasibility constraints and “scaling realism” for everyday parts. [24]

#### 11) Stretchable and biodegradable self-healing conductors for multifunctional electronics

**Authors/organisation:** Tae Min Jang[25] et al.

**Venue/type:** Peer-reviewed paper (journal: Science Advances[26]; open access via PubMed Central)

**Publication date:** September 2024

**Link:** <https://pmc.ncbi.nlm.nih.gov/articles/PMC11373598/>

**Why it matters:** Reports rapid/complete recovery of electrical conductivity (~1000 S/cm) and stretchability (~500%) after repeated damage using dynamic bonding; demonstrates system-level self-healing electronics (including sensing) in a biomedical context—evidence for “smart polymer” integration with functional electronics and practical form factors. [27]

#### 12) Preparation and properties of double-layer phenolic/polyurethane coated isophorone diisocyanate self-healing microcapsules

**Authors/organisation:** Liye Yuan[28] et al.

**Venue/type:** Peer-reviewed paper (journal: Scientific Reports[29])

**Publication date:** 09 September 2024

**Link:** <https://www.nature.com/articles/s41598-024-68917-3>

**Why it matters:** Demonstrates improved capsule robustness (thermal/ageing/environmental stability) and coating-level performance: with 10 wt.% capsules in an epoxy coating, scratch corrosion testing shows successful repair and no corrosion after 7 days in 10 wt.% NaCl; reported self-healing efficiency in tensile terms is ~57.9%—useful, quantitative evidence for extrinsic healing in protective coatings. [30]

#### 13) Self-healable, recyclable, and mechanically robust vitrimer composite for high-performance triboelectric nanogenerators and self-powered wireless electronics

**Authors/organisation:** Araz Rajabi-Abhari[31] et al.

**Venue/type:** Peer-reviewed paper (journal: Nano Energy[32])

**Publication date:** 01 December 2024

**Link:** <https://www.sciencedirect.com/science/article/pii/S2211285524010589>

**Why it matters:** Shows a vitrimer composite enabling both self-healing/recyclability and strong functional output in a device: power density ~2571 mW/m<sup>2</sup> (15 N, 6 Hz) and output

voltage ~1325 V, with demonstration use cases (e.g., watchband, wireless transmission)—evidence that self-healing polymers can be embedded into functional “smart” energy-harvesting hardware rather than isolated material samples. [33]

**14) Enhanced method in the design of microvascular self-healing system in a composite structure based on a Newtonian healing agent**

**Authors/organisation:** Ameer S. Zirjawi[34] et al.

**Venue/type:** Peer-reviewed paper (Journal of Materials Research and Technology; open access via ScienceDirect)

**Publication date:** March–April 2025

**Link:** <https://www.sciencedirect.com/science/article/pii/S2238785425000924>

**Why it matters:** Provides engineering-level design guidance for microvascular self-healing architectures (e.g., identifying ~0.5 mm channel diameter as meeting design criteria) and ties it to impact-loading scenarios (e.g., ~31.55 J impact leading to ~10.79 kN maximum contact force), supporting plausibility for vascular delivery approaches in structural composites. [35]

**15) Preparation and properties study of self-healing anticorrosive coating based on MCM-41 nanocontainer and triazinyl corrosion inhibitor**

**Authors/organisation:** Guangqun Cao[36] et al.

**Venue/type:** Peer-reviewed paper (Scientific Reports)

**Publication date:** 01 July 2025

**Link:** <https://www.nature.com/articles/s41598-025-06528-2>

**Why it matters:** Demonstrates a “smart + self-healing” anticorrosive coating concept (pH-responsive inhibitor release) with quantitative electrochemical performance: after 30 days immersion, impedance magnitude  $|Z|$  at 0.01 Hz is reported as ~3 orders of magnitude higher than pure epoxy—evidence for adaptive, environment-responsive protection rather than purely passive barrier coatings. [37]

**16) Eco-friendly thermally activated vitrimer resin composites with self-healing mechanical and electrically conducting functional capabilities**

**Authors/organisation:** L. Amorim[38] et al.

**Venue/type:** Peer-reviewed paper (journal: Next Materials; open access via ScienceDirect)

**Publication date:** January 2026

**Link:** <https://www.sciencedirect.com/science/article/pii/S2949822825009992>

**Why it matters:** Reports a bio-based epoxy/vitrimer system (58% renewable carbon) and MWCNT composites with >80% repair efficiency upon heating, adhesive stress ~4 MPa, and “functional conductivity recovery,” including Joule-heating-enabled repair—direct evidence toward the ART claim that polymers can self-heal and also adapt/restore functional properties (electrical) with low-power triggering. [39]

**Maturity score (1–7) and reasoning**

**Final maturity score:** 5

**Rationale (mapping evidence to rubric):**

This ART is best treated as a **bundle** with uneven maturity: certain self-healing polymer products (notably surface-protection films/coatings) are already commercially delivered, while more structurally ambitious “self-healing + smart multifunctional” polymer platforms for load-bearing composites and embedded electronics remain largely in prototype/PoC stages. [40]

- **What rules out levels 1–3:**
- Multiple peer-reviewed papers demonstrate **quantified, device-relevant performance** (e.g., rapid strength recovery and multi-cycle healing in fibre/vitrimer composites; functional electronics that regain high conductivity and stretchability after cutting; device-level energy-harvesting outputs with self-healing materials). [\[41\]](#)
- There is evidence of **real commercial delivery** in at least one self-healing polymer segment (urethane paint-protection films with stated self-healing function and long warranties). [\[42\]](#)
- **Why the score is not higher (what is missing for level 6):**
- For the **broader** “everyday parts that fail by microcracks/wear” vision (especially structurally loaded components and multifunctional composites), the dossier is still dominated by **laboratory and early engineering demonstrations**, not large-scale field qualification (multi-year service) and not clear evidence of ramping manufacturing volumes for structural self-healing polymers. [\[43\]](#)
- Although standardisation is emerging (a sign of maturation), widespread adoption of standard test methods, procurement specifications, and long-term reliability datasets for diverse environments (hot/wet/UV/chemical exposure, cyclic fatigue, repeated healing over many cycles) remains a major gating item for “scale to mainstream structural parts.” [\[44\]](#)

In short: the **operating principles and prototypes** are clearly demonstrated and in some niches **already commercial**, but the **full two-capability platform** (autonomous repair + adaptive multifunctionality across broad part categories) is not yet broadly deployed at industrial scale—consistent with a **level 5** “post-PoC / early commercial + multiple actors preparing production-scale pathways” position. [\[45\]](#)

#### Subcomponent maturity breakdown and aggregation

- **Commercial self-healing polymer films/coatings (scratch-healing polyurethane films): maturity ~6**  
Evidence: vendor product bulletins describing self-healing function, material construction, and long warranties indicate customer delivery (commercial products), even if the use case is primarily surface damage rather than structural crack healing. [\[42\]](#)
- **Self-healing structural polymer networks and composites (intrinsic vitrimer networks; high-toughness self-healing architectures; microvascular design): maturity ~4**  
Evidence: strong lab and engineering demonstrations (e.g., rapid >95% recovery in minutes for vitrimer resin; multi-cycle interface healing; design methodologies for vascular delivery), but limited evidence here of certified field trials or scaled manufacturing of structural parts. [\[46\]](#)
- **Self-healing + functional “smart” electronics/energy devices (conductors, polymer electrolytes, TENGs): maturity ~4**  
Evidence: device-level prototypes with quantified recovery (conductivity recovery and stretchability; battery cycling retention; energy-harvesting outputs) demonstrate plausibility, but these remain mainly research/early prototype demonstrations rather than widely shipped product classes. [\[47\]](#)
- **Responsive / adaptive coatings (thermochromic self-healing; pH-responsive anticorrosion): maturity ~4**  
Evidence: papers show combined self-healing with adaptive behaviours (thermal response;

pH-triggered inhibitor release) and quantitative corrosion-resistance metrics, but scaling and qualification across application sectors remains largely unproven in the dossier. [48]

- **Testing and sustainability/scale-enabling infrastructure (standard methods; lifecycle/circularity analysis): maturity ~5**

Evidence: a recent CEN Workshop Agreement explicitly addressing how to test repairable/self-healing composites signals movement toward comparability and qualification; the sustainability/circularity review frames design constraints for scalable adoption. [49]

### Aggregation to one score:

Given the ART's breadth and the clear split between (i) some commercially deployed self-healing polymer surface products (~6) and (ii) broader structural/multifunctional platforms mostly in PoC/prototype stages (~4), an average-based assessment centres on ~5 as the most defensible single maturity score. [50]

[1] [3] [4] [9] [12] [13] [19] [44] [45] [49] [https://www.cencenelec.eu/media/CEN-CENELEC/CWAs/RI/cwa17896\\_2022.pdf](https://www.cencenelec.eu/media/CEN-CENELEC/CWAs/RI/cwa17896_2022.pdf)

## ART 07.047 Nano-Catalysts & Advanced Coatings

### ART extraction

**A) Primary capability claimed (core “what it does”)** - Engineer surface/interface behaviour at the **nanometre scale** to increase catalytic activity per gram, improve selectivity (fewer by-products), and add designed surface functions (e.g., corrosion resistance, low friction,

controlled wetting) without redesigning whole systems.

- Deploy as **retrofittable form factors**: catalyst cartridges/structured catalyst inserts, thin films, or spray/dip/ALD/PVD layers compatible with existing pipes, vessels, filters, radomes, components.
- Incorporate “smart” elements: **durability against deactivation/wear**, and (in more advanced versions) **self-indicating/self-reporting** coatings plus data-driven recipes/quality metrics updated over time.

**B) Key sub-components / variants (technology bundle threads) - Nano-catalysts with maximised active-site efficiency** (e.g., single-atom / single-site catalysts; defect/interface-engineered supports; high-entropy oxides; nanostructured electrocatalysts). [1]

- **Structured catalysts & washcoats** (monolith/honeycomb supports; slurry rheology → coating quality control; anti-shedding and anti-clogging coatings; scale-up fabrication). [2]
- **Advanced protective coatings** (corrosion-resistant multilayers; hybrid PVD/ALD sealing; conformal barrier films; thermal-spray wear coatings). [3]
- **Large-area functional wetting/anti-fouling coatings** (durable sprayable superhydrophobic and related surfaces). [4]
- **Smart / self-reporting & self-healing coatings** (microcapsules, fluorophores, mechanochromic indicators; visual/fluorescent wear or corrosion cues; “early warning”). [5]
- **Digital optimisation and repeatability** (use of ML/automation for recipe screening; modelling degradation vs signal; scale-up workflows). [6]

**C) Maturity indicators that would count as “good evidence” for this ART - Relevant-environment durability**: multi-hundred to multi-thousand-hour stability under heat, contaminants, salinity, pressure, abrasion or cyclic conditions (not just short lab runs). [7]

- **Scale-up proof**: kilogram-scale catalyst synthesis with preserved structure/performance; large-area or high-volume coating runs; repeatable QC metrics. [8]
- **System integration**: catalysts validated in device-relevant configurations (e.g., membrane electrode assemblies / electrolyzers) and coatings validated in real use cases. [9]
- **Deployability evidence**: field trials in operational industrial settings; documented maintenance/inspection advantages (e.g., self-reporting signals), and credible pathways to manufacturing/qualification. [10]

**Evidence (10–20 recent, reliable sources)**

#### 1) **Cost-efficient and stable electrolysis of reverse osmosis water using a Co–RuO<sub>2</sub>-enabled PEM electrolyser**

- Authors/organisation: Hao Liu[11] et al.
- Venue/type: peer-reviewed paper (Nature Catalysis[12])
- Publication date: **Jan 2026** (Published 07 Jan 2026)
- Link (URL): <https://www.nature.com/articles/s41929-025-01456-w>
- Why it matters: Demonstrates a **device-level prototype** where a standard PEM water electrolyser runs **2,000 h at 1.0 A cm<sup>-2</sup>** on RO-grade impure water with a reported **10.2 μV h<sup>-1</sup> degradation rate**, directly supporting plausibility of impurity-tolerant, nano-engineered catalyst interfaces and their durability constraints. [13]

#### 2) **Universal scalable production of single-atom catalysts for antibiotic wastewater treatment**

- Authors/organisation: Xunheng Jiang[14] et al.

- Venue/type: peer-reviewed paper (Nature Water[15])
- Publication date: **Jan 2026** (Published 09 Jan 2026)
- Link (URL): <https://www.nature.com/articles/s44221-025-00561-1>
- Why it matters: Reports **kilogram-scale** production of single-/dual-atom catalysts with **up to 14 wt% metal loading** and validates stability/efficacy in a **near-industrial continuous-flow reactor** with limited Fe leaching—direct evidence for scalability and real-reactor maturity. [16]

### 3) Intrinsic metal-support interactions break the activity–stability dilemma in electrocatalysis

- Authors/organisation: Lingxi Zhou[17] et al.
- Venue/type: peer-reviewed paper (Nature Communications[18])
- Publication date: **Oct 2025** (Published 01 Oct 2025)
- Link (URL): <https://www.nature.com/articles/s41467-025-63397-z>
- Why it matters: Presents an integrated Ru/TiMnO<sub>x</sub> electrode with reported **multi-fold mass activity gains** and **up to 3,000 h** stable operation, illustrating that nanoscale interface design can materially shift the activity–durability trade-off (a core constraint in the ART description). [19]

### 4) A corrosion-resistant RuMoNi catalyst for efficient and long-lasting seawater oxidation and anion exchange membrane electrolyzer

- Authors/organisation: Xin Kang[20] et al.
- Venue/type: peer-reviewed paper (Nature Communications)
- Publication date: **Jun 2023** (Published 17 Jun 2023)
- Link (URL): <https://www.nature.com/articles/s41467-023-39386-5>
- Why it matters: Shows a nanostructured electrocatalyst sustaining **>3,000 h at 500 mA cm<sup>-2</sup>** in alkaline seawater conditions and demonstrates an AEM electrolyser reaching **1,000 mA cm<sup>-2</sup> at 1.72 V**, supporting plausibility of corrosion-resistant nano-catalysts and device-level integration. [21]

### 5) A single site ruthenium catalyst for robust soot oxidation without platinum or palladium

- Authors/organisation: Yuanfeng Li[22] et al.
- Venue/type: peer-reviewed paper (Nature Communications)
- Publication date: **Nov 2023** (Published 06 Nov 2023)
- Link (URL): <https://www.nature.com/articles/s41467-023-42935-7>
- Why it matters: Single-atom Ru on ceria is reported to deliver **~9× higher TOF** than Ru nanoparticles and to rival commercial Pt-based soot oxidation performance while addressing volatility/stability—evidence for “more activity per gram” and stability engineering at the surface lattice level. [23]

### 6) Single Ru(II) ions on ceria as a highly active catalyst for abatement of NO

- Authors/organisation: Konstantin Khivantsev[24] et al.
- Venue/type: peer-reviewed paper (Journal of the American Chemical Society[25])
- Publication date: **Feb 2023** (Published 22 Feb 2023)
- Link (URL): <https://pubmed.ncbi.nlm.nih.gov/36812067/>
- Why it matters: Reports that **only 0.1–0.5 wt% Ru** (atomically dispersed) can achieve high NO reduction activity by CO at low temperatures, supporting feasibility of ultra-low-loading nano-catalysts that reduce precious-metal dependence. [26]

### 7) **Highly Efficient Fabrication of Kilogram-Scale Palladium Single-Atom Catalysts for the Suzuki–Miyaura Cross-Coupling Reaction**

- Authors/organisation: Hao Zhang[27] et al.
- Venue/type: peer-reviewed paper (2entity[2] ["organization", "ACS Applied Materials & Interfaces", "materials journal"] [2])
- Publication date: **Nov 2022** (Epub 21 Nov 2022; in issue Dec 2022)
- Link (URL): <https://pubmed.ncbi.nlm.nih.gov/36410052/>
- Why it matters: Describes a **direct ball-milling** method with reported **~100% productivity** and **kilogram-scale** Pd single-atom catalyst synthesis, plus concrete activity metrics (TOF reported in the abstract), directly addressing the ART's "consistent nanostructures at scale" constraint. [28]

### 8) **Water-retaining slurry washcoat for high-loading and robust CuMnO<sub>x</sub> structured catalyst toward durable monoxide oxide purification from real flue gas**

- Authors/organisation: Xuan Zhang[29] et al.
- Venue/type: peer-reviewed paper (Separation and Purification Technology[30])
- Publication date: **Mar 2025** (1 March 2025 issue)
- Link (URL): <https://www.sciencedirect.com/science/article/abs/pii/S1383586624033240>
- Why it matters: Explicit **industrialisation evidence**: reports structured catalyst washcoats with **high loading (>160 kg/m<sup>3</sup>)**, **powder shedding <1 wt%**, and a **2 m<sup>3</sup> scale-up** validated in a **steel plant** achieving **>90% CO removal for >1,440 h**—strong maturity signal for retrofittable catalyst-coated structures. [31]

### 9) **Durable superhydrophobic coatings for prevention of rain attenuation of 5G/weather radomes**

- Authors/organisation: Jinfei Wei[32] et al.
- Venue/type: peer-reviewed paper (Nature Communications)
- Publication date: **May 2023** (Published 19 May 2023)
- Link (URL): <https://www.nature.com/articles/s41467-023-38678-0>
- Why it matters: Demonstrates a spray-applied coating design that targets **mechanical robustness + weather resistance** simultaneously and reports **large-scale preparation and practical application** on 5G/weather radomes, directly matching the ART's "sprayable retrofit functional coating" form factor. [33]

### 10) **Dense Al<sub>2</sub>O<sub>3</sub> sealing inhibited high hydrostatic pressure corrosion of Cr/GLC coating**

- Authors/organisation: Shuyu Li[34] et al.
- Venue/type: peer-reviewed paper (npj Materials Degradation[35])
- Publication date: **May 2024** (Published 04 May 2024)
- Link (URL): <https://www.nature.com/articles/s41529-024-00469-3>
- Why it matters: Shows ALD as a scalable "engineered interface" approach: adding an **ALD Al<sub>2</sub>O<sub>3</sub> sealing layer** to a multilayer coating reduces corrosion current density by **>2 orders of magnitude** across **0.1–15 MPa** pressure range—direct durability evidence under harsh conditions (deep-sea relevant). [36]

### 11) **Al<sub>2</sub>O<sub>3</sub>–ZnO atomic layer deposited nanolaminates for improving mechanical and corrosion properties of sputtered CrN coatings**

- Authors/organisation: Elias Kaady[37] et al.
- Venue/type: peer-reviewed paper (Thin Solid Films[38])
- Publication date: **Oct 2022** (1 October 2022 issue)

- Link (URL): <https://www.sciencedirect.com/science/article/abs/pii/S0040609022003881>
- Why it matters: Demonstrates hybrid **PVD/ALD architectures** where ALD nanolaminates act as sealing/interlayers to improve corrosion and mechanical performance (measured via electrochemistry and nanoindentation), supporting plausibility of scalable thin-film “retrofit” protective stacks. [39]

#### 12) Tribological Performance of Thin HVOF-Sprayed WC–CoCr Coatings Fabricated Employing Fine Powder Feedstock

- Authors/organisation: Kaveh Torkashvand[40] et al.
- Venue/type: peer-reviewed paper (Journal of Thermal Spray Technology[41])
- Publication date: **Dec 2022** (Published 08 Dec 2022; issue date 2023)
- Link (URL): <https://link.springer.com/article/10.1007/s11666-022-01506-w>
- Why it matters: Provides quantified wear results for an industrially relevant, scalable coating method (HVOF), with reported **specific wear rates on the order of  $10^{-8} \text{ mm}^3 \cdot \text{N}^{-1} \cdot \text{m}^{-1}$** —direct evidence for the ART’s durability/value proposition around friction and wear losses. [42]

#### 13) A novel self-healing coating with mechanically-triggered self-reporting properties: Color and fluorescence dual damage indications

- Authors/organisation: Yue Wang[43] et al.
- Venue/type: peer-reviewed paper (Progress in Organic Coatings[44])
- Publication date: **Feb 2024**
- Link (URL): <https://www.sciencedirect.com/science/article/abs/pii/S0300944023007439>
- Why it matters: Demonstrates “embedded markers that indicate wear/loss of function”: microcapsules release a dye (DCF) upon damage to yield **visible colour change and fluorescence**, and links this to self-healing via shape-memory epoxy—credible lab evidence for self-reporting coatings. [45]

#### 14) Real-time and visual monitoring coating damage and metal corrosion ... quantified via a Python program integrated into smartphones

- Authors/organisation: Tianfei Qi[46] et al.
- Venue/type: peer-reviewed paper (Sensors and Actuators B: Chemical[47])
- Publication date: **Sep 2024** (15 September 2024)
- Link (URL): <https://www.sciencedirect.com/science/article/abs/pii/S0925400524007330>
- Why it matters: Implements a **self-reporting** corrosion/damage monitoring concept with quantitative readout (Python/smartphone workflow) and indicator chemistry, directly supporting the ART’s “monitoring via embedded markers” and the bridge to digital lifecycle tracking. [48]

#### 15) COAT4LIFE periodic reporting: Eco-friendly corrosion protective coatings based on smart nanotechnology platforms for a circular economy

- Authors/organisation: European Commission[49] / CORDIS[50] project reporting page
- Venue/type: authoritative government programme report (H2020 project periodic reporting)
- Publication date: **Nov 2025** (Last update 11 Nov 2025; reporting period 2023–2025)
- Link (URL): <https://cordis.europa.eu/project/id/101007430/reporting>
- Why it matters: Explicitly frames a combined pathway of **corrosion sensing + anticorrosion nanoadditives**, including stated integration of sensing **TRL 3–4** with protective systems **TRL >5** and subsequent **scale-up and demonstration**, aligning with the ART bundle’s mixed-maturity reality. [51]

#### 16) Atomic Layer Deposition solutions and wafer-scale ALD technology (MEMS Sensors & Actuators Webinar)

- Authors/organisation: Beneq[52] technical webinar slide deck
- Venue/type: vendor technical presentation (equipment/process characteristics and scale approaches)
- Publication date: **Jun 2023** (8 Jun 2023)
- Link (URL): <https://www.semi.org/sites/semi.org/files/2023-06/Beneq%20-%20SEMI%20MEMS%20%26%20SENSOR%20Webinar%20Final.pdf>
- Why it matters: Documents ALD as an industrially supported deposition route emphasising **pinhole-free conformal films**, process windows, and throughput scaling via **batch processing** (and references to roll-to-roll/spatial concepts), relevant to the ART's "scalable application methods" and maturity of enabling equipment ecosystems. [53]

#### 17) Coatings Made by Atomic Layer Deposition for the Protection of Materials from Atomic Oxygen in Space

- Authors/organisation: Leo Nyman[54] et al.
- Venue/type: peer-reviewed conference paper (IOP Conf. Series: Materials Science and Engineering; open-access via Aalto University[55] repository)
- Publication date: **2023**
- Link (URL): <https://aaltodoc.aalto.fi/items/9fa4670c-d562-4271-a4f2-f3fb1e83dcb9>
- Why it matters: Reports **20 nm** ALD metal-oxide films deposited at **125 °C** on polymers/PCBs and then exposed to atomic oxygen at an European Space Agency[56] ESTEC facility; the coated samples show improved survivability versus uncoated substrates—direct evidence of thin-film coatings as engineered interfaces for extreme environments. [57]

#### Maturity score (1–7) and reasoning

##### Final maturity score

##### Final maturity score for the ART (bundle): 5

This ART is best interpreted as a **technology family** where some threads (structured catalyst washcoats; industrial thin-film deposition methods) are already near- or in industrial practice, while other threads (field-tunable catalysts; self-reporting/self-healing coatings with validated long-term reliability) remain at lab-to-PoC stages. [58]

#### Evidence-to-rubric mapping

##### Why the evidence rules out scores 1–3 (i.e., it is beyond “just theory” or early lab verification)

- Multiple sources show **device-relevant prototypes** and **long-duration operation**, not only short lab demonstrations. Examples include a PEM electrolyser operating **2,000 h at 1.0 A cm<sup>-2</sup>** on RO-grade impure water (catalyst/interface engineering in a practical configuration) and multiple **~3,000 h** durability demonstrations in electrocatalysis contexts. [59]
  - There is also direct **field-scale validation** of structured catalysts (2 m<sup>3</sup> scale) in an operational industrial setting (steel plant flue gas), aligned with the ART's “retrofit, cartridge/insert/washcoat” deployment model. [2]
- These collectively exceed “lab prototype exists” (score 3) by including **system integration + durability + scale/field trial** evidence.

### Why the evidence supports score 5 rather than 4

- Score 4 (PoC) is strongly supported in several subthreads, but the dossier also includes **clear post-PoC scale-up signals**: kilogram-scale catalyst synthesis with preserved performance, near-industrial continuous-flow reactor validation for water treatment, and an actual large-volume structured catalyst deployment/validation for real flue gas. [8]
- The EU COAT4LIFE programme explicitly describes moving from sensing elements around **TRL 3–4** into **scale-up and demonstration**, consistent with active development and multiple actors bridging R&D to deployment (a hallmark of score 5 in a bundled field). [51]

### What is still missing to justify score 6 (and therefore also 7)

- The rubric for 6 requires strong, recent evidence that **products are being delivered to customers in increasing amounts**, with expansion of production financed, and that application areas are broadening with economies of scale. Across this ART bundle, the dossier shows **compelling prototypes, long tests, and selective field deployments**, but it does not, as a whole, document **broad multi-customer shipment volumes** or sustained market-scale roll-out for the newest nano-engineered catalyst/coating formulations (especially smart/self-reporting variants). [60]
- Durability remains a recognised barrier in several subthreads (abrasion, harsh chemicals, inhibitor/sensor longevity). While individual studies show impressive durability (thousands of hours; high-pressure corrosion improvements), translating that into **standardised qualification + widespread procurement** is not demonstrated consistently across the whole family in the last-4-years evidence set. [61]

### Sub-component maturity breakdown and aggregation approach

(Estimates are mapped to the rubric and then averaged, because applications and value capture differ materially across subthreads.)

- **Structured catalysts / washcoats for industrial gas purification → 6**  
Evidence: scale-up to **2 m<sup>3</sup>** and steel-plant flue-gas validation with **>90% efficiency for >1,440 h** indicates delivery-like maturity for that slice. [2]
- **Nano-catalysts in electrolyzers / harsh electrochemical environments → 4–5**  
Evidence: thousands-of-hours stability and device-level demonstrations are strong PoC / advanced prototype signals, but customer shipment scaling is not evidenced here. [62]
- **Scalable synthesis of high-loading single-atom catalysts for water treatment → 5**  
Evidence: kilogram-scale synthesis plus validation in a near-industrial continuous-flow reactor suggests post-PoC scale-up, but not yet broad market delivery evidence. [63]
- **Advanced protective coatings via scalable deposition (ALD/PVD/thermal spray) → 6**  
(enabling toolchains are mature; specific formulations vary)  
Evidence: quantified corrosion/wear improvements and mature deposition routes, with vendor documentation indicating industrial scale equipment ecosystems; still formulation-dependent for end-use qualification. [64]
- **Smart/self-reporting coatings and digital/visual monitoring methods → 3–4**  
Evidence: convincing laboratory demonstrations of colour/fluorescence reporting and smartphone/Python quantification, but limited long-term field reliability/standards qualification evidence. [65]

**Aggregation:** Averaging these (with the bundle's "frontier" elements pulling down the mature deposition and structured-catalyst slices) produces an overall **ART maturity  $\approx 5$** , reflecting a field with **validated prototypes and selective real-world deployments**, but without comprehensive evidence of **broad, increasing customer deliveries across the full technology family** in the last four years. [66]

## ART 07.048 High-Entropy Alloys & Advanced Metals

### ART extraction

#### Primary capability

- Engineer **advanced metallic materials** (high-entropy alloys and related compositionally complex alloys) that can **shift or escape conventional strength-ductility-temperature trade-offs**, especially for harsh environments (high temperature, oxidation/corrosion, irradiation). [1]
- Deliver **selectable “recipes”** (composition + processing + heat treatment) that remain compatible with **industrial routes** such as powder metallurgy, coatings, and metal additive manufacturing (AM), enabling near-net-shape parts and/or protective surfaces. [2]

- Couple alloy design to **data/computation + high-throughput experimentation** (materials acceleration platforms, ML/CALPHAD/DFT screening, automated testing/characterisation) to speed up discovery and down-selection. [3]

#### Key sub-components or variants

- **Refractory HEAs (RHEAs)** for  $>\sim 1000$  °C structural use (mechanical stability, creep strength, oxidation resistance). [4]
- **Precipitation-strengthened / dual-phase HEAs** (e.g., A2/B2, FCC/BCC/B2) targeting strength-ductility synergy and thermal stability. [5]
- **AM-processable HEAs/MEAs** (LPBF/L-PBF, DED/L-DED, laser cladding) with strategies for crack mitigation and defect control. [6]
- **HEA coatings** for corrosion/steam oxidation and nuclear “accident tolerant fuel” (ATF) coating concepts, including irradiation-coupled degradation mechanisms. [7]
- **Powder feedstock & processing windows** (atomised / PREP powders, particle-size effects, flowability, defect formation). [8]
- **Oxidation-resistant “bond coat” compositions** (Ni-Co-Cr-Al-Fe HEAs) designed via ML and validated experimentally versus incumbent MCrAlY. [9]
- **Materials acceleration platforms** integrating AI + high-throughput manufacturing and automated characterisation for metallic HEAs. [10]

#### Maturity indicators that would constitute strong evidence

- **Repeatable processing windows** for dense/crack-free builds (e.g., quantified porosity/defect fractions; demonstrated across multiple builds and geometries). [11]
- **Service-relevant property datasets**, including high-temperature creep/oxidation, fatigue, corrosion/steam exposure, irradiation effects, and long-duration stability (100s–1000s of hours). [12]
- **Manufacturing and qualification pathways**: powder specifications, joining/heat treatment standards development, and documented qualification concerns (especially irradiation/corrosion). [13]
- **Industrial involvement beyond lab scale**: consortia programmes, funded scale-up, prototype components, and clear evidence of pre-commercial prototypes. [14]
- **Comparative benchmarks** vs incumbent alloys/coatings (e.g., oxidation resistance vs MCrAlY; corrosion vs AFA/AFA-like alloys; creep vs conventional high-T alloys). [15]

#### Evidence (10–20 recent, reliable sources)

##### Peer-reviewed experimental papers and open-access technical literature

##### 1) Additive manufacturing of defect-free TiZrNbTa refractory high-entropy alloy with enhanced elastic isotropy via in-situ alloying of elemental powders

- **Author(s)/org**: Shahryar Mooraj[16] et al.
- **Type**: Peer-reviewed paper (open access)
- **Date**: Feb 2024 (published 16/02/2024)
- **Link**: <https://www.nature.com/articles/s43246-024-00452-0>
- **Why it matters**: Demonstrates a **nearly defect-free** RHEA made by L-PBF using **in-situ alloying of elemental powders**, with an identified processing window and reported

comparability to as-cast properties plus improved elastic isotropy—direct plausibility evidence for AM-compatible RHEA platforms and process-window engineering. [17]

## 2) Intrinsic factors responsible for brittle versus ductile nature of refractory high-entropy alloys

- **Author(s)/org:** Tomohito Tsuru[18] et al.
- **Type:** Peer-reviewed paper (open access)
- **Date:** Feb 2024 (published 24/02/2024)
- **Link:** <https://www.nature.com/articles/s41467-024-45639-8>
- **Why it matters:** Provides combined experimental/theoretical insight into why prototypical RHEAs can be **ductile to cryogenic temperatures (77 K) or brittle at room temperature**, clarifying feasibility constraints and guiding composition/process choices—key to making RHEAs “engineerable” rather than one-off curiosities. [19]

## 3) Crack mitigation in additively manufactured AlCrFe<sub>2</sub>Ni<sub>2</sub> high-entropy alloys through engineering phase transformation pathway

- **Author(s)/org:** Xizhen Dong[20] et al.
- **Type:** Peer-reviewed paper (open access)
- **Date:** Jun 2024 (published 18/06/2024)
- **Link:** <https://www.nature.com/articles/s43246-024-00542-z>
- **Why it matters:** Shows a concrete route to suppress **solid-state cracking** in an AM HEA by controlling cooling rate and phase evolution: high cooling rates yield crack-susceptible BCC/B2, whereas lower cooling rates promote FCC precipitation and ~10% ductility, improving crack resistance—direct evidence that “narrow manufacturing windows” are tractable with physics-guided process control. [21]

## 4) Creep behavior of a precipitation-strengthened A2-B2 refractory high entropy alloy

- **Author(s)/org:** Liu Yang[22] et al.
- **Type:** Peer-reviewed paper (open access)
- **Date:** Apr 2025 (15/04/2025 issue date)
- **Link:** <https://www.sciencedirect.com/science/article/pii/S1359645425001193>
- **Why it matters:** Measures high-temperature creep on a Ta-Mo-Ti-Cr-Al **A2+B2** two-phase microstructure, explicitly positioning “refractory HEA superalloy” analogues as credible high-T structural candidates rather than purely strength-at-room-temperature materials. [23]

## 5) Ultra-high temperature oxidation resistant refractory high entropy alloys fabricated by laser melting deposition: Al concentration regulation and oxidation mechanism

- **Author(s)/org:** Ziyi Zhou[24] et al.
- **Type:** Peer-reviewed paper
- **Date:** 2023 (journal article; DOI page indicates 2023)
- **Link:** <https://www.sciencedirect.com/science/article/abs/pii/S0010938X23005796>
- **Why it matters:** Reports a laser-deposited Al<sub>x</sub>(CrMoTaTi)<sub>1-x</sub> RHEA where higher Al (x=0.15) can form an **external Al<sub>2</sub>O<sub>3</sub> scale during oxidation in air at 1300 °C**, directly supporting plausibility for oxidation-resistant high-T RHEAs. [25]

## 6) Enhancing high-temperature corrosion and cracking resistance of a dual-phase high entropy alloy through surface grinding

- **Author(s)/org:** Kai Chen[26] et al.

- **Type:** Peer-reviewed paper
- **Date:** 2025 (DOI page indicates 2025)
- **Link:**  
<https://www.sciencedirect.com/science/article/abs/pii/S0010938X25005542>
- **Why it matters:** Evaluates an Al-enriched dual-phase HEA under **600 °C steam**, reporting corrosion/cracking resistance benefits linked to phase-specific Al content (BCC phase reaching ~16.63 wt% Al) and surface state—evidence for “workhorse” HEAs/coatings aimed at aggressive steam/corrosion environments. [27]

**7) High temperature steam oxidation behavior of AlCrNbTiZr high entropy alloy coating modified by irradiation-induced atomic diffusion**

- **Author(s)/org:** Zhaoming Yang[28] et al.
- **Type:** Peer-reviewed paper
- **Date:** Sep 2025 (01/09/2025 issue date)
- **Link:**  
<https://www.sciencedirect.com/science/article/abs/pii/S0257897225005778>
- **Why it matters:** Directly targets a nuclear-relevant constraint—**irradiation effects on subsequent steam oxidation**—by Au-ion irradiating AlCrNbTiZr HEA coatings and testing at 1000–1200 °C; this is maturity-relevant because qualification for harsh environments depends on understanding coupled degradation mechanisms. [29]

**8) A precipitation strengthened high entropy alloy with high (Al+Ti) content for laser powder bed fusion: Synergizing intrinsic hot cracking resistance and ultrahigh strength**

- **Author(s)/org:** Shiwei Wu[30] et al.
- **Type:** Peer-reviewed paper
- **Date:** Oct 2023 (01/10/2023 issue date)
- **Link:**  
<https://www.sciencedirect.com/science/article/abs/pii/S1359645423005232>
- **Why it matters:** Demonstrates an HEA designed to be **crack-free in LPBF without preheating** despite high (Al+Ti) content (~7.4 wt%), directly addressing AM manufacturability bottlenecks (cracking/printability) that block scaling. [31]

**9) Effect of heat treatment on mechanical and corrosion properties of an Al<sub>0.8</sub>CrFe<sub>2</sub>Ni<sub>2</sub> alloy processed by laser powder bed fusion**

- **Author(s)/org:** Dimitrios Vogiatzief[32] et al.
- **Type:** Peer-reviewed paper
- **Date:** Aug 2023 (25/08/2023 issue date)
- **Link:**  
<https://www.sciencedirect.com/science/article/abs/pii/S0925838823011192>
- **Why it matters:** Reports **crack-free, high-density (>99.9%)** LPBF coupons from prealloyed powder with microstructure and property tuning via heat treatments (FCC → FCC+BCC-B2 precipitates) and corrosion testing in 3.5% NaCl—evidence of post-processing routinisation (heat treatment) and realistic property trade-offs. [33]

**10) Effect of annealing on microstructure and mechanical properties of AlCrFe<sub>2</sub>Ni<sub>2</sub> medium entropy alloy fabricated by laser powder bed fusion additive manufacturing**

- **Author(s)/org:** Tianyi Han[34] et al.
- **Type:** Peer-reviewed paper
- **Date:** Apr 2022 (06/04/2022 issue date)

- **Link:**

<https://www.sciencedirect.com/science/article/abs/pii/S0921509322002763>

- **Why it matters:** Systematically studies annealing (750–1050 °C) to obtain **strength–ductility synergy** in LPBF AlCrFe<sub>2</sub>Ni<sub>2</sub>, supporting the ART claim that these materials become practical through “recipe-like” combinations of composition + processing + heat treatment. [35]

11) **Additive manufacturing of a functionally graded high entropy alloy using a hybrid powder-bed wire-based direct energy deposition approach**

- **Author(s)/org:** Yao Lu[36] et al.

- **Type:** Peer-reviewed paper (open access)

- **Date:** Feb 2023 (05/02/2023 issue date)

- **Link:** <https://www.sciencedirect.com/science/article/pii/S2214860423000374>

- **Why it matters:** Demonstrates **functionally graded HEA** manufacture (Al content gradient) by hybrid DED, achieving continuous FCC → BCC(+FCC) transitions and quantifying strengthening contributions—evidence for HEAs as configurable “families” rather than single compositions. [37]

12) **High entropy alloys amenable for laser powder bed fusion: A thermodynamics guided machine learning search**

- **Author(s)/org:** Ran Duan[38] et al.

- **Type:** Peer-reviewed paper

- **Date:** Apr 2024 (25/04/2024 issue date)

- **Link:**

<https://www.sciencedirect.com/science/article/abs/pii/S2214860424002410>

- **Why it matters:** Presents a thermodynamics-informed ML strategy to predict LPBF printability using parameters like liquid temperature range and viscosity—directly supporting the feasibility of a design stack linking **computational screening → manufacturable HEAs**. [39]

13) **Microstructure and mechanical properties of Co<sub>31.5</sub>Cr<sub>7</sub>Fe<sub>30</sub>Ni<sub>31.5</sub> high-entropy alloy powder produced by plasma rotating electrode process and its applications in additive manufacturing**

- **Author(s)/org:** Xiaping Fan[40] et al.

- **Type:** Peer-reviewed paper (open access)

- **Date:** Jul–Aug 2024

- **Link:** <https://www.sciencedirect.com/science/article/pii/S223878542401528X>

- **Why it matters:** Links **powder production quality** (PREP powders; particle size 20–106 μm) to AM outcomes, reporting tensile properties for laser cladding AM bulk (UTS ~481 MPa, elongation ~35.9%) and identifying defects (pores/prior particle boundaries) driving brittle fracture in cold spray—evidence for manufacturability and scale-up constraints residing in feedstock and consolidation routes. [41]

**Authoritative lab / metrology / consortium reports and programmes**

14) **Advanced Manufacturing Techniques and Compositions of High Entropy Alloys for Nuclear Applications**

- **Author(s)/org:** Pacific Northwest National Laboratory[42] (prepared for US DOE)

- **Type:** National lab technical report

- **Date:** Aug 2024

- **Link:**

[https://www.pnnl.gov/main/publications/external/technical\\_reports/PNNL-36488.pdf](https://www.pnnl.gov/main/publications/external/technical_reports/PNNL-36488.pdf)

- **Why it matters:** A programme-level survey plus experimental work that explicitly evaluates **AM routes (DED/SLM) and solid-phase processing (e.g., friction surface layer deposition)** and builds a decision matrix for nuclear-relevant HEA candidates; it also highlights performance claims (e.g., for NASA GRX-810) and frames where qualification gaps remain. [43]

#### 15) **Summary Report of the High Entropy Alloys for Nuclear Applications Workshop**

- **Author(s)/org:** OECD Nuclear Energy Agency[44]

- **Type:** Authoritative international workshop report (EGISM/NEA)

- **Date:** Mar 2024 (document dated March 2024; issued 12/03/2024)

- **Link:** [https://www.oecd-neo.org/upload/docs/application/pdf/2024-03/nea\\_nsc\\_r\\_2023\\_9.pdf](https://www.oecd-neo.org/upload/docs/application/pdf/2024-03/nea_nsc_r_2023_9.pdf)

- **Why it matters:** Provides a conservative, deployment-focused view: HEAs likely need **reliable manufacturing processes**, are expected (given probable high costs) to be used **mostly as coatings**, and face qualification challenges (notably irradiation-property data)—direct maturity evidence about barriers to market adoption. [45]

#### 16) **Complex Precipitation Behavior in a Co-free High Entropy Alloy during Aging**

- **Author(s)/org:** National Institute of Standards and Technology[46]

- **Type:** Government lab publication record (journal paper with detailed abstract)

- **Date:** Sep 2024 (published 11/09/2024)

- **Link:** <https://www.nist.gov/publications/complex-precipitation-behavior-co-free-high-entropy-alloy-during-aging>

- **Why it matters:** Gives highly specific, time-resolved precipitation kinetics ( $L_{1/2}/B_2/\chi$ ) at 650 °C and quantifies microstructure evolution (e.g., >50% precipitate volume fraction after 120 h) in a Co-free HEA—critical for moving from “interesting composition” to **certifiable heat-treatment schedules and microstructural stability**. [47]

#### 17) **SOLID-MAP: Development of a Materials Acceleration Platform for High-Entropy Alloys**

- **Author(s)/org:** VTT Technical Research Centre of Finland[48]

- **Type:** Peer-reviewed paper (publisher final version; CC BY)

- **Date:** Dec 2025 (published 01/12/2025)

- **Link:** <https://cris.vtt.fi/ws/portalfiles/portal/118860004/s11665-025-11504-y.pdf>

- **Why it matters:** Describes an end-to-end HEA materials acceleration platform combining active-learning surrogate modelling + CALPHAD/DFT screening with **high-throughput DED of elemental powders** and automated XRD/electron microscopy + AI analysis, reporting a “significant speed-up” in development—direct evidence for the ART’s “database + high-throughput testing” pillar. [10]

#### 18) **Machine learning and high-throughput computational guided development of high temperature oxidation-resisting Ni-Co-Cr-Al-Fe based high-entropy alloys**

- **Author(s)/org:** Xiaobo Tan[49] et al.

- **Type:** Peer-reviewed paper (open access)

- **Date:** Apr 2025 (published 04/04/2025)
- **Link:** <https://www.nature.com/articles/s41524-025-01568-8>
- **Why it matters:** Uses ML + high-throughput computation with experimental validation to identify non-equiatomic Ni-Co-Cr-Al-Fe HEAs with oxidation resistance **surpassing the state-of-the-art bond coat MCrAlY**, illustrating the emerging “design-select-validate” loop needed for near-market adoption in turbines. [9]

#### 19) **SUSustainable production of High Entropy Alloys from Secondary metals (SUSHEAS)**

- **Author(s)/org:** CORDIS[50] (European Commission project fact sheet)
- **Type:** EU programme / consortium project record
- **Date:** Aug 2025 (EC signature date 06/08/2025; start 01/11/2025)
- **Link:** <https://cordis.europa.eu/project/id/101236968>
- **Why it matters:** Signals funded, multi-party work on a specific bottleneck—**sustainable HEA production from secondary metals**, with explicit mention of AI optimisation, manufacturing/characterisation, and prototype demonstration—evidence that actors are actively tackling material supply/cost and process scale-up constraints. [51]

#### **Maturity score (1–7) and reasoning**

**Final maturity score: 4**

#### **Why this is at least level 4 (rules out levels 1–3):**

- The ART is far beyond theory or basic lab principle: multiple peer-reviewed studies demonstrate **repeatable, parameterised manufacturing pathways** (e.g., defined processing windows for near-defect-free L-PBF RHEAs; crack-mitigation via phase-transformation pathway engineering) that directly address known blockers like cracking and porosity. [52]
- There is strong evidence of **application-relevant performance testing** (creep at elevated temperatures for A2/B2 RHEAs; oxidation in air at 1300 °C with protective Al<sub>2</sub>O<sub>3</sub> scale formation; steam corrosion and cracking resistance at 600 °C; irradiation-coupled steam oxidation of HEA coatings). [53]
- The ecosystem is not only academic: national-lab programmes and metrology organisations are publishing design/qualification-relevant work (e.g., PNNL’s AM methods and candidate down-selection; NIST’s time-resolved precipitation evolution). [54]

These collectively indicate **Proof-of-Concept functionality**: the materials can be made via relevant industrial processes (AM, coatings) with controlled microstructures and measured properties that credibly target commercial requirements for harsh environments. [55]

#### **Why it is not level 5 (what is missing):**

- Level 5 would require clear evidence that **multiple well-capitalised market actors are competing to launch production prototypes** (pilot lines, qualification campaigns, production tooling, customer trials with timelines). The recent record is dominated by high-quality R&D and funded programmes, but even authoritative assessments stress that deployment will require **reliable manufacturing processes** and that qualification—especially post-irradiation behaviour—is hard and still developing. [56]
- The evidence base here shows **promising prototypes and design frameworks**, but not yet broad proof of scaled supply (standardised bar stock/sheet/wire powders at industrial volumes), certified joining/surface treatment standards, or long-duration service qualification datasets across many compositions. [57]

### Sub-score breakdown and aggregation

Because “High-Entropy Alloys & Advanced Metals” is a **family** spanning bulk alloys, AM-tailored grades, coatings, and discovery platforms, maturity varies by sub-thread:

- **AM-processable bulk HEAs / MEAs (LPBF/L-PBF/DED): ~4** — Crack mitigation and high-density builds with post-heat-treatment tunability are demonstrated, indicating PoC manufacturability (but not yet widespread product qualification). [58]
- **High-temperature structural RHEAs (creep + oxidation): ~3–4** — Strong experimental progress (creep studies; oxidation-protective scales at 1300 °C), but still largely pre-certification and composition-specific. [59]
- **HEA coatings for harsh/water/steam/irradiation environments: ~3–4** — Clear lab demonstrations including irradiation-coupled oxidation behaviour, but authoritative reports emphasise qualification challenges and a likely early role as coatings. [7]
- **Accelerated discovery / materials acceleration platforms for HEAs: ~3–4** — Integrated computational + high-throughput experimental pipelines are demonstrated, and oxidation-resistant candidates outperform incumbents in targeted comparisons, but this is still early in terms of standard industrial adoption as a routine “platform”. [60]

**Aggregation to one score:** The dominant value proposition across variants is **the same functional claim** (tailored, manufacturable advanced alloys for harsh environments), but maturity is uneven; taking an **evidence-weighted average** across the most application-proximate sub-threads (AM-processable alloys and coatings), the dossier supports **overall level 4** today. [61]

## ART 07.049 Advanced CO<sub>2</sub> Capture Materials for Climate Mitigation

### 1. ART extraction

**A) Primary capability claimed (core “what it does”)** - Engineer CO<sub>2</sub>-selective capture media based on metal–organic frameworks (MOFs), leveraging tuneable pore chemistry/geometry to preferentially bind CO<sub>2</sub> in complex gas streams (varying CO<sub>2</sub> %, humidity, and contaminants). - Package these materials into practical, modular contactor formats (e.g., coated structures, pellets/monoliths/laminates, fibres, cartridges) compatible with conventional ducting, blowers, and control systems. - Enable relatively low-intensity regeneration (temperature swing, vacuum/pressure swing, humidity swing, and potentially electro-assisted/rapid heating) to deliver a concentrated CO<sub>2</sub> stream for downstream handling.

**B) Key sub-components / variants (technology sub-threads) - MOF chemistries optimised for specific separations:** post-combustion (CO<sub>2</sub>/N<sub>2</sub>), direct air capture (DAC; ~400 ppm), and higher-concentration industrial streams. - **Moisture/impurity tolerance:** stability to H<sub>2</sub>O, O<sub>2</sub>, NO<sub>x</sub>/SO<sub>x</sub>, and other trace contaminants; mitigation of sorbent degradation pathways. - **Shaping and contactor engineering:** structured beds (laminates, monoliths, extrudates, membranes), hollow fibres and composite architectures to reduce pressure drop and improve kinetics/heat transfer. - **Regeneration approaches:** VSA/PSA/TSA and rapid/electrified heating (e.g., Joule heating) to reduce heat-transfer bottlenecks and energy penalties. - **Manufacturing scale-up:** synthesis routes that reduce solvent use, shorten cycle times, increase yields, and support tonnage-scale output with consistent performance. - **Operational monitoring and service model:** modular replacement/tuning (cartridge swaps, operating “recipes”) rather than wholesale equipment replacement.

**C) Maturity indicators that constitute evidence** - Demonstrated **humid/flue-gas-relevant performance** (breakthrough, purity/recovery/productivity) in structured formats, not just powder isotherms. - **Cycle durability evidence** (hundreds to thousands of cycles; minimal capacity loss) and at least some **realistic impurity exposure** studies (O<sub>2</sub>, SO<sub>2</sub>, etc.). - **Pilot or field trials** in industrial environments (e.g., cement, hydrogen/SMR, refineries), with time-on-stream and post-mortem sorbent analysis. - Credible signs of **manufacturing feasibility** (high-yield/low-solvent synthesis routes; mechanochemical or microwave acceleration; documented scale-up). - Evidence of **industrial or government-backed programmes**

moving from PoC to engineering design/FEED and techno-economic analysis (TEA), plus multiple well-capitalised actors.

## 2. Evidence (10–20 recent, reliable sources)

### 1) Experimental demonstration of humid post-combustion CO<sub>2</sub> capture by vacuum swing adsorption using CALF-20

Organisation(s): University of Alberta[1]; University of Calgary[2]

Venue/type: Peer-reviewed journal article (Adsorption, Springer Nature)

Publication date: **February 2025** (published 09 Feb 2025)

Link: <https://link.springer.com/article/10.1007/s10450-025-00600-z>

Annotation: Reports VSA experiments on *structured* CALF-20 across humidity (13–70% RH), showing minimal performance difference vs dry operation at 13–45% RH and reporting multi-day runs (hundreds of cycles) with **minimal CO<sub>2</sub>-capacity loss after ~10,000 cycles**—directly addressing moisture tolerance and cyclic durability in a process-relevant configuration. [3]

### 2) Gas adsorption and framework flexibility of CALF-20 explored via experiments and simulations

Organisation(s): Collaborative work including Svante[4] (industry collaboration mentioned)

Venue/type: Peer-reviewed, open-access article (Nature Communications)

Publication date: **May 2024** (published 09 May 2024)

Link: <https://www.nature.com/articles/s41467-024-48136-0>

Annotation: Combines experiments and modelling to explain CALF-20's CO<sub>2</sub> and H<sub>2</sub>O adsorption behaviour and the role of water-framework interactions/hydrogen-bond networks in its hydrophobic response—evidence for scientific plausibility of performance under humid conditions and a basis for rational “family” tuning across operating regimes. [5]

### 3) CALF-20 obtained by mechanochemical synthesis for temperature swing adsorption CO<sub>2</sub> capture: a thermodynamic and kinetic study

Organisation(s): Italian research institutes (CNR/ENEA listed on the article page)

Venue/type: Peer-reviewed, open-access article (Chemical Engineering Journal)

Publication date: **2025** (journal year 2025)

Link: <https://www.sciencedirect.com/science/article/pii/S138589472500765X>

Annotation: Demonstrates CALF-20 made via reduced-solvent mechanochemical synthesis and tested dynamically in a lab fixed-bed TSA reactor across 28–130 °C and 3–20% CO<sub>2</sub>, reporting **up to ~2.55 mmol g<sup>-1</sup> capacity** and stable multi-cycle regeneration—direct evidence that greener synthesis routes can preserve cyclic, process-relevant performance. [6]

### 4) MOF-carbon fibre composites for electrically driven CO<sub>2</sub> regeneration under direct air capture conditions

Organisation(s): (Authors listed on article page; academic team)

Venue/type: Peer-reviewed article (Chemical Engineering Journal)

Publication date: **2025** (journal year 2025)

Link:

<https://www.sciencedirect.com/science/article/abs/pii/S1385894725111534>

Annotation: Develops a MOF/carbon-fibre composite enabling **Joule-heating (ETSA) regeneration**; reports DAC-relevant CO<sub>2</sub> capacities (e.g., **~2.32 mmol g<sup>-1</sup> at 400 ppm, 25 °C**

for one formulation) and **complete desorption in ~4 minutes** with >95% retention and **~66% higher regeneration efficiency** vs conventional TSA—concrete evidence for electro-assisted regeneration pathways and structured formats. [7]

#### 5) **Efficient solvent-free mechanochemical synthesis of CALF-20 for carbon dioxide capture**

Organisation(s): (Authors; paper in CrystEngComm)

Venue/type: Peer-reviewed research article (CrystEngComm, RSC)

Publication date: **2025** (received June 2025; accepted August 2025 per the manuscript metadata)

Link: <https://www.rsc.org/suppdata/d5/ce/d5ce00632e/d5ce00632e1.pdf>

Annotation: Provides an experimentally detailed, **solvent-free mechanochemical route** to CALF-20 (supporting information with procedural detail and stability testing), supporting the plausibility of manufacturing routes that reduce solvent dependence while maintaining capture-relevant properties. [8]

#### 6) **Enhancing CO<sub>2</sub> capture via fast microwave-assisted synthesis of the CALF-20 metal-organic framework**

Organisation(s): (Authors; peer-reviewed article hosted on PMC)

Venue/type: Peer-reviewed article (Inorganic Chemistry; open full text via PMC)

Publication date: **2025**

Link: <https://pmc.ncbi.nlm.nih.gov/articles/PMC11863388/>

Annotation: Reports microwave synthesis cutting time drastically (e.g., “92% reduction” vs solvothermal) and improving yields (e.g., **~97%**), with characterisation showing comparable structure and improved adsorption/selectivity; also notes an industrial-relevance context including a **1 tonne/day** cement-plant demonstration claim and explicitly frames CALF-20 as advanced TRL—useful (but interpret cautiously) for maturity signals plus concrete manufacturing acceleration metrics. [9]

#### 7) **Mechanistic studies of oxidative degradation in diamine-appended MOFs exhibiting cooperative CO<sub>2</sub> capture**

Organisation(s): Lawrence Berkeley National Laboratory[10]; University of California, Berkeley[11] (authors’ affiliations indicated via associated records)

Venue/type: Peer-reviewed article (Journal of the American Chemical Society; bibliographic record) + detailed experimental manuscript

Publication date: **July 2025**

Link: <https://www.osti.gov/biblio/2574016>

Annotation: Provides mechanistic evidence that O<sub>2</sub> exposure can degrade diamine functionalities (impacting chemisorption) while parent frameworks remain largely intact, identifying degradation products and proposing radical-mediated pathways—directly addressing a key “lifetime under real-world impurities” constraint and guiding more robust formulations. [12]

#### 8) **Impact of SO<sub>2</sub> on the stability and CO<sub>2</sub> capture performance of a diamine-appended MOF**

Organisation(s): University of California, Berkeley[11] (author manuscript hosted)

Venue/type: Peer-reviewed article (JACS; author manuscript)

Publication date: **2022** (Epub Oct 2022 per indexing)

Link: <https://escholarship.org/content/qt3p36h4c4/qt3p36h4c4.pdf>

Annotation: Experimental study focused on SO<sub>2</sub> effects on a leading diamine-appended MOF system, directly targeting contaminant robustness—an essential plausibility/maturity gate for deploying MOF sorbents in “dirty” industrial flue gas. [13]

#### 9) Scalable formation of diamine-appended MOF hollow fibre sorbents for post-combustion CO<sub>2</sub> capture

Organisation(s): Georgia Institute of Technology[14]; ExxonMobil[15]

Venue/type: Peer-reviewed article (JACS Au; open full text via PMC)

Publication date: **June 2022** (collection date 27 Jun 2022; accepted Apr 2022)

Link: <https://pmc.ncbi.nlm.nih.gov/articles/PMC9241006/>

Annotation: Demonstrates a *manufacturable contactor format* (MOF/polymer composite **hollow fibres spun via a conventional dry-jet wet-quench method**), explicitly aimed at diluted streams such as NGCC flue gas—evidence for compatibility with scalable processing and real contactor geometries beyond powders. [16]

#### 10) CO<sub>2</sub> capture from wet flue gas using a water-stable and cost-effective MOF (MIL-120)

Organisation(s): Oregon State University (correspondence indicated); U.S. Department of Energy[17] (hosted via OSTI)

Venue/type: Peer-reviewed, open-access article (Cell Reports Physical Science; PDF via OSTI)

Publication date: **July 2023** (19 Jul 2023)

Link: <https://www.osti.gov/servlets/purl/2000685>

Annotation: Reports breakthrough capture from **dry and wet flue gas** with measured capacities (**~1.215 vs 1.118 mmol g<sup>-1</sup>** dry vs wet) and a reported CO<sub>2</sub> affinity (**~44 kJ mol<sup>-1</sup>**), providing concrete evidence that water-stable, lower-cost MOF chemistries can work under humid flue gas conditions. [18]

#### 11) Rapid Cycle Temperature Swing Adsorption using CALF-20 MOF structured adsorbent for cement carbon capture

Organisation(s): Svante[4]; TotalEnergies[19]; Lafarge Canada (listed on the preprint page)

Venue/type: Conference-linked technical paper hosted as SSRN preprint (labelled as such)

Publication date: **February 2023** (posted 06 Feb 2023)

Link: <https://ssrn.com/abstract=4349347>

Annotation: Reports **~900 hours of field-testing** of a CALF-20 structured sorbent in a **real cement kiln flue gas** context—materially stronger maturity evidence than lab-only studies, while also highlighting contaminant/lifetime evaluation in situ. [20]

#### 12) Engineering study of a solid-sorbent (MOF) CO<sub>2</sub> capture technology at a steam methane reforming (H<sub>2</sub>) plant

Organisation(s): Linde[21]; BASF[22]; Svante[4]; National Energy Technology Laboratory[23] (host)

Venue/type: Authoritative programme/engineering presentation (DOE/NETL project material)

Publication date: **September 2023** (document dated 09/01/2023)

Link: [https://netl.doe.gov/sites/default/files/netl-file/23CM\\_PSCC1\\_Shah.pdf](https://netl.doe.gov/sites/default/files/netl-file/23CM_PSCC1_Shah.pdf)

Annotation: Documents a DOE-supported, site-specific engineering design/TEA effort for integrating a MOF-based solid sorbent capture system at an SMR H<sub>2</sub> plant, including project objectives and deployment planning—evidence that MOF sorbents are being engineered into full-plant designs rather than remaining lab concepts. [24]

### 13) **Field/pilot performance and TEA signals from structured sorbent bed development (CALF-20)**

Organisation(s): (NETL-hosted carbon management project material; includes “1 TPD” pilot references)

Venue/type: Technical programme presentation (DOE/NETL carbon management review material)

Publication date: **2023** (embedded in file path and meeting context; slide deck includes operational-hour reporting)

Link: [https://netl.doe.gov/sites/default/files/netl-file/23CM\\_PSCC30\\_Fagundo.pdf](https://netl.doe.gov/sites/default/files/netl-file/23CM_PSCC30_Fagundo.pdf)

Annotation: Reports pilot/durability indicators such as **500 hours** post-mortem analysis (noting negligible loss for the MOF section vs contaminant sensitivity for amine sections) and **accumulated operating hours** plus TEA assumptions—useful maturity evidence around lifetime and cost-relevant operation (noting the presentation context). [25]

### 14) **Sorbents for Carbon Capture (programme overview and R&D framing)**

Organisation(s): National Energy Technology Laboratory[23]

Venue/type: Authoritative government lab factsheet / programme material

Publication date: **August 2023**

Link: <https://netl.doe.gov/sites/default/files/2023-08/NETL-sorbents-2023.pdf>

Annotation: Summarises the DOE/NETL R&D framing for sorbent-based capture (including goals, constraints, and pathways), supporting maturity evaluation by showing sustained, structured public-sector investment and a pipeline of projects beyond single-lab efforts. [26]

### 15) **A holistic platform for accelerating sorbent-based carbon capture**

Organisation(s): Multi-institution academic team (paper focus: platform)

Venue/type: Peer-reviewed article (Nature)

Publication date: **2024** (published 2024)

Link: <https://www.nature.com/articles/s41586-024-07933-6>

Annotation: Presents an integrated platform approach to accelerate identification/validation of carbon-capture sorbents—relevant to the ART’s “configurable capture family” claim by supporting faster iteration from material discovery to process-relevant screening. [27]

### 16) **Compendium of Carbon Capture Technology (DOE/NETL)**

Organisation(s): National Energy Technology Laboratory[23]

Venue/type: Government programme repository/compendium (technical summaries of projects)

Publication date: **2024 update**

Link: <https://netl.doe.gov/carbon-management/carbon-capture/compendium>

Annotation: Indicates a large active portfolio (e.g., “technology sheets for 145 active and recent R&D projects”), supporting maturity assessment by evidencing breadth of ongoing capture R&D and multiple parallel development tracks (including sorbents and point-source capture). [28]

### 17) **Direct Air Capture 2022 (IEA analysis)**

Organisation(s): International Energy Agency[29]

Venue/type: Authoritative international agency report/analysis

Publication date: **April 2022** (published 01 Apr 2022)

Link: <https://www.iea.org/reports/direct-air-capture-2022>

Annotation: Establishes DAC as an emerging but scaling-critical climate technology and summarises the early deployment landscape (e.g., counts of operating facilities and the scale-up implied by net-zero pathways), providing market/scale context for why higher-performance solid sorbents (including MOF-based) matter and what “maturity” must ultimately achieve at system level. [30]

### 3. Maturity score (1–7) and reasoning

#### A) Final maturity score: 5

#### B) Why this score fits the rubric (evidence-to-rubric mapping)

##### What rules out levels 1–3 (the “it’s not just theory or a lab trick” bar):

Multiple sources demonstrate process-relevant prototypes and performance evidence beyond single-material equilibrium testing. A peer-reviewed study reports humid VSA operation with structured MOF sorbent and documents multi-day cycling with minimal capacity loss after ~10,000 cycles. [3] Government/industry-linked materials document site-specific engineering and techno-economic work for integrating MOF solid sorbents into an H<sub>2</sub> plant context (an “engineering design” maturity indicator rather than lab-only work). [24] Field testing in an industrial cement flue gas environment (~900 hours) further rules out a purely laboratory-prototype stage. [20]

##### What justifies level 5 (vs stopping at level 4):

Level 5 requires either (i) several well-capitalised actors competing to develop production prototypes post-PoC or (ii) clear evidence that production prototypes are in a finishing phase with investments made to launch production. The evidence shows:

- **Industrial ecosystem + engineering progression:** DOE/NETL-hosted work involves major industrial participants (e.g., Linde, BASF, and a MOF-sorbent capture developer) conducting site-specific engineering design and TEA for a real industrial plant. [24]
- **Pilot/field validation signals:** field-testing in cement and programme materials referencing pilot-scale configurations and durability/post-mortem results that distinguish sorbent sensitivity to contaminants. [31]
- **Manufacturing acceleration evidence:** multiple recent synthesis papers show clear progress toward scalable, faster, higher-yield routes (microwave-assisted yields ~90–99% for some conditions and reduced synthesis time; mechanochemical approaches aimed at reducing solvents while preserving performance), strengthening the plausibility of tonnage-scale manufacturing pathways. [32]

Together, this is more consistent with a post-PoC push toward production prototypes than with a single isolated PoC. [33]

##### What is still missing to justify level 6 (products delivered to customers in increasing amounts):

The dossier shows strong pilot/field and engineering evidence, but it does not provide robust, independently verifiable indicators that MOF-based capture *products* (standardised modules/cartridges) are being delivered broadly to multiple customers “in increasing amounts,” nor the kind of market-wide shipment/scale expansion data expected at level 6. Current evidence is strongest for advanced pilots, field testing, and engineering design/TEA rather than documented, ramping commercial deliveries. [34]

### C) Sub-component maturity breakdown (bundle logic) and aggregation to one score

- **MOF sorbent chemistry and durability under O<sub>2</sub>/SO<sub>2</sub>/H<sub>2</sub>O:** maturity ~4 (PoC-level durability mechanisms and mitigation strategies are increasingly well-characterised, but broadly generalisable, “drop-in” robustness across contaminants remains an active research frontier). Key sources: oxidative degradation mechanisms in diamine-appended systems (2025) and SO<sub>2</sub> stability studies (2022), plus humid cyclic operation results (2025). [35]
- **Shaped/structured contactor formats (fibres/structured adsorbents):** maturity ~4–5 (demonstrated scalable fabrication routes such as hollow-fibre composite sorbents; deployment-relevant structured beds in VSA studies). Key sources: scalable MOF hollow fibre fabrication (2022) and structured-bed humid VSA operation (2025). [36]
- **Regeneration approaches (TSA/VSA and electrified rapid heating):** maturity ~4–5 (credible prototype demonstrations exist, including ETSA/Joule heating composites under DAC-relevant concentrations, but industrial standardisation and scaling remain uneven). Key source: ETSA MOF/carbon-fibre composite with rapid desorption and quantified efficiency gains (2025). [7]
- **Manufacturing scale-up pathways:** maturity ~4–5 (multiple credible routes—microwave, mechanochemical—show clear process intensification and yield improvements; still, supply-chain resilience and consistent megaton-scale production are not yet evidenced as “routine”). Key sources: microwave-assisted synthesis with high yields (2025) and mechanochemical synthesis + process testing (2025). [32]
- **System integration and industrial pilots/engineering:** maturity ~5 (engineering studies + field testing indicate serious commercialisation work with major industrial actors). Key sources: DOE/NETL engineering design study (2023) and cement field testing (2023). [37]

**Aggregation rationale:** Because the ART’s end-user functionality is largely consistent across variants (modular MOF-based capture media in engineered contactor formats, regenerated by swing processes), it is reasonable to score near the leading edge of demonstrated system integration while acknowledging that not all MOF chemistries are equally mature. The combined evidence supports a **level-5** overall assessment (production-prototype push with well-capitalised actors and advanced pilots), rather than averaging down to level 4 (which would underweight the field/engineering evidence). [34]

## ART 07.050 Graphene and Nanotube Composites for Lightweight Strength

### ART extraction

- **Primary capability (claimed)**
- **Structural composites with higher specific performance:** graphene- and/or carbon-nanotube–reinforced polymers/laminates that meaningfully improve

**strength-to-weight, fatigue/delamination resistance, and crack tolerance** over baseline fibre-reinforced polymers (FRPs). [1]

- **Multifunctionality via conductivity:** engineered electrical/thermal conduction in otherwise insulating laminates enabling **embedded sensing** (strain, delamination, impact damage) through resistance/impedance measurements and simple electronics. [2]
- **Partial manufacturing compatibility:** nanomaterials added via **masterbatches, sprays/coatings, interleaves, or resin mixing**, keeping some alignment with established composite manufacturing routes. [3]
- **Key sub-components / variants (sub-threads)**
- **CNT/graphene in resin (“nano-filled matrix”):** direct mixing into epoxies/thermosets; properties sensitive to dispersion state, CNT geometry, and mixing protocol. [4]
- **Interlaminar toughening interleaves:** CNT- or graphene-based veils/films/interleaves placed between plies to target delamination and mode-I/II fracture toughness. [5]
- **Surface modification / coated fibres:** CNT-coated glass/carbon fibres and graphene oxide surface treatments to improve interfacial adhesion and/or create conductive sensing layers. [6]
- **Self-sensing architectures:** grids, embedded sensing layers, electrotopography, or resistance mapping to localise impact damage/delamination. [7]
- **Process control and inspection:** metrics+automation (e.g., computer vision) to quantify dispersion quality for repeatable performance at scale. [8]
- **Standards, purity, and safety envelope:** standardised characterisation methods (graphene structure; CNT impurity quantification) and occupational exposure sampling guidance that shape scalable industrial handling. [9]
- **CNT fibres/yarns as “engineered fabrics”:** CNT fibre tows/yarns as conductive, lightweight structural textile candidates usable in composites and sensing. [10]
- **Maturity indicators that would count as strong evidence**
- **Repeatable mechanical delamination/fatigue gains** (mode-I/II fracture toughness, CAI, lap-shear/joint durability) demonstrated on **multi-ply laminates**, not just neat resin coupons, using industrially relevant processes. [11]
- **Embedded sensing validated against ground truth** (e.g., DIC, tomography) with quantified localisation error, sensitivity, and minimal mechanical penalty. [12]
- **Scale-up enablers:** industrial masterbatches, roll-to-roll/continuous processing demonstrations, and in-line QC methods that reduce batch-to-batch variance. [13]
- **Standardisation / metrology readiness:** clear, adopted standards (or late-stage drafts) for graphene structure, CNT purity/impurities, and workplace sampling protocols. [9]
- **Market proximity:** evidence of qualified parts, field trials, or shipped products specifically for structural composite applications (not only lab prototypes). (This type of evidence is comparatively weaker in the sources found below.) [14]

## 2. Evidence (10–20 recent, reliable sources)

### 1) Effects of carbon nanotube (CNT) geometries on the dispersion characterizations and adhesion properties of CNT reinforced epoxy composites

- Authors/organisation: Dawei Zhang[15] et al.
- Venue/type: Peer-reviewed paper in Composite Structures[16]
- Publication date: 15 Sep 2022
- Link: <https://www.sciencedirect.com/science/article/abs/pii/S0263822322007000>
- What it shows and why it matters: Demonstrates that **CNT diameter and length materially affect dispersion and adhesive performance**, with larger-diameter CNTs dispersing more uniformly and “normal-length” CNTs giving higher lap-shear strength/toughness than shorter CNTs—evidence that **process/material reproducibility is a real maturity bottleneck** (geometry → dispersion → joint reliability). [17]

### 2) Technical Report: Occupational Exposure Sampling for Engineered Nanomaterials

- Authors/organisation: NIOSH[18] (by Hodson & Eastlake)
- Venue/type: Authoritative government technical report
- Publication date: Jul 2022 (NIOSH Publication No. 2022-153)
- Link: <https://www.cdc.gov/niosh/docs/2022-153/default.html>
- What it shows and why it matters: Provides consolidated workplace sampling guidance for engineered nanomaterials including **carbon nanotubes/nanofibres**, reflecting that **EHS sampling/controls are necessary for scale-up** and can influence cost and regulatory acceptance of CNT handling in composite manufacturing. [19]

### 3) Comprehensive Data via Spectroscopy and Molecular Dynamics of Chemically Treated Graphene Nanoplatelets

- Authors/organisation: NIST[20] (paper by Olasunbo Farinre[21] et al.)
- Venue/type: Government-hosted peer-reviewed journal publication page (paper in *Data*)
- Publication date: 30 Mar 2022 (page updated Nov 2022)
- Link: <https://www.nist.gov/publications/comprehensive-data-spectroscopy-and-molecular-dynamics-chemically-treated-graphene>
- What it shows and why it matters: Provides **measurement datasets and characterisation** for chemically treated graphene nanoplatelets—relevant to the ART’s practical constraints around **impurities, repeatability, and quality control** of graphene feedstocks before they can reliably reinforce composites. [22]

### 4) ISO/AWI 21356-1 — Nanotechnologies: Structural characterization of graphene — Part 1: Graphene from powders and dispersions

- Authors/organisation: ISO[23]
- Venue/type: Standards work item (authoritative; under development)
- Publication date: New project approved 09 Aug 2023
- Link: <https://www.iso.org/standard/87572.html>
- What it shows and why it matters: Specifies a **sequence of methods** and protocols to characterise graphene (layer number/thickness, lateral size, disorder, alignment, specific surface area) from powders/dispersions—evidence that **metrology/standardisation infrastructure is catching up**, which is a prerequisite for vendor qualification and scalable composites. [24]

### 5) ISO/DTS 23690:2023 — Nanotechnologies: Multiwall carbon nanotubes — Determination of carbon impurity content by thermogravimetric analysis

- Authors/organisation: ISO technical specification preview (source shows ISO copyright

marking)

- Venue/type: Standards document (technical specification / draft technical specification; treat cautiously as “preview”)

- Publication date: 2023 (document header indicates ISO/DTS 23690:2023)

- Link:

<https://cdn.standards.iteh.ai/samples/76660/4aee3524509f4419928f475a1ca86e06/ISO-DTS-23690.pdf>

- What it shows and why it matters: Defines a method (TGA under CO<sub>2</sub>) to quantify **carbon impurities in MWCNT samples**, explicitly noting that impurities affect nanomaterial properties—directly aligned to the ART’s constraint about **impurity control and repeatable quality** for structural reliability. [25]

#### 6) Multiscale nano-integration in the scarf-bonded patches for enhancing the performance of the repaired secondary load-bearing aircraft composite structures

- Authors/organisation: Serra Topal[26] et al.

- Venue/type: Peer-reviewed paper in Carbon[27]

- Publication date: Feb 2023

- Link: <https://www.sciencedirect.com/science/article/abs/pii/S0008622322010983>

- What it shows and why it matters: Demonstrates **upscaled integration** of thermally exfoliated graphene oxide and a CNT epoxy masterbatch (Epocyl 128-06) into scarf repair patches; reports stiffness recoveries of **~109.9%, 99.7%, and 99.3%** (depending on nano-integration strategy), supporting plausibility for **interfaces/joints/repairs**—a known weak point for composites. [28]

#### 7) Computer vision and machine learning for assessing dispersion quality in carbon nanotube / resin systems

- Authors/organisation: Henry P. Diehl[29] et al.

- Venue/type: Peer-reviewed paper in Carbon (same journal as above; not repeated as entity)

- Publication date: Sep 2023

- Link: <https://www.sciencedirect.com/science/article/abs/pii/S000862232300475X>

- What it shows and why it matters: Trains a computer-vision model on segmented microscopy images to rapidly, quantitatively assess **dispersion quality** in CNT-loaded commercial resins, claiming accuracy/repeatability comparable to current methods—direct evidence for **process control/inspection** needed for scaling. [8]

#### 8) Hierarchical toughening and self-diagnostic interleave for composite laminates manufactured from industrial carbon nanotube masterbatch

- Authors/organisation: Biltu Mahato[30] et al.

- Venue/type: Peer-reviewed paper in Composites Science and Technology[31]

- Publication date: 20 Oct 2023

- Link: <https://www.sciencedirect.com/science/article/abs/pii/S0266353823003354>

- What it shows and why it matters: Uses an **industrially available CNT masterbatch** painted onto prepregs to create conductive interleaves for **damage self-diagnostics** during double-cantilever-beam tests; also shows a key maturity caveat: a **0.6 wt%** interleave *reduced* Mode-I toughness (~80% detrimental), whereas **7.5 wt%** improved initiation (~27%)—highlighting that scalable formulations exist but robustness/process windows remain immature. [32]

### 9) Improved interlaminar property of carbon fiber/epoxy composites with polyurethane/RGO core-shell structure fibrous mat

- Authors/organisation: Nan Zheng[33] et al.
- Venue/type: Peer-reviewed paper in Composites Communications[34]
- Publication date: Dec 2023
- Link: <https://www.sciencedirect.com/science/article/abs/pii/S2452213923002565>
- What it shows and why it matters: Reports interlaminar gains from an electrospun PU veil decorated with reduced graphene oxide: **Mode-I toughness +170%, Mode-II toughness +21%, and interlaminar shear strength +14%**, supporting the ART's claim that nano-reinforcements can bridge/deflect cracks and raise delamination resistance using laminate-compatible interleaves. [35]

### 10) In-situ monitoring of crack growth and fracture behavior in composite laminates using embedded sensors of rGO coated fabrics and GnP paper

- Authors/organisation: Mohamed Salman Sikandar Bathusha[36] et al.
- Venue/type: Peer-reviewed paper (bibliographic record in institutional repository)
- Publication date: 2024 (repository record lists "01.01.2024"; journal volume 365)
- Link: <https://khazna.ku.ac.ae/en/publications/in-situ-monitoring-of-crack-growth-and-fracture-behavior-in-compo/>
- What it shows and why it matters: Reports use of **rGO-coated fabric** and **graphene nanoplatelet paper** as embedded sensors for in-situ crack/fracture monitoring in laminates—directly aligned to the ART's embedded-sensing pathway (conductive reinforcement as a sensing network). [37]

### 11) Monitoring of static and vibration responses of laminated composite materials using integrated carbon nanotube fibers

- Authors/organisation: Jandro L. Abot[38] et al.
- Venue/type: Peer-reviewed paper (Composites Science and Technology; journal entity already introduced)
- Publication date: 26 Jul 2024
- Link: <https://www.sciencedirect.com/science/article/abs/pii/S0266353824002641>
- What it shows and why it matters: Demonstrates CNT yarn/fibre sensors integrated into glass-fibre/epoxy laminates; sensors track deformation **instantaneously** via electrical resistance under four-point bending and capture sinusoidal vibration cycles, supporting feasibility of **continuous condition monitoring** without heavyweight instrumentation. [39]

### 12) Structural Health Monitoring of GFRP laminates with CNT-coated glass fiber sensing layer after low-velocity impact using Electrical Resistance Tomography

- Authors/organisation: Zijie Zhao[40] et al.
- Venue/type: Peer-reviewed open-access paper in Nanomaterials[41]
- Publication date: Published 09 Sep 2024
- Link: <https://www.mdpi.com/2079-4991/14/17/1462>
- What it shows and why it matters: Embeds an MWCNT-coated glass-fibre sensing layer and uses ERT to localise impact damage; reports **~4.5% error** in detected damage area and notes the sensing layer does not adversely affect impact response (with a nuance: energy absorption behaviour occurs ~10% earlier), evidencing progress toward usable SHM-enabled composites. [42]

### 13) Damage monitoring on inter-lamination of GFRP via the resistance change of the MWCNT@GF sensor

- Authors/organisation: Changfu Tang[43] et al.
- Venue/type: Peer-reviewed paper (Composites Communications; journal entity already introduced)
- Publication date: Dec 2024
- Link: <https://www.sciencedirect.com/science/article/abs/pii/S2452213924003280>
- What it shows and why it matters: Embeds a PVD-manufactured MWCNT-coated glass-fibre sensor within laminates and correlates resistance changes with interlaminar shear damage, including monotonic and cyclic tests; claims a quantitative relation between shear damage and relative resistance—supporting the ART’s “self-reporting delamination/damage” potential. [44]

### 14) Versatile fabrication of CNT yarn composites by in-situ interfacial polymerization of polyetherimide

- Authors/organisation: Michael N. Durso[45] et al.
- Venue/type: Peer-reviewed paper in Composites Part B: Engineering[46]
- Publication date: Dec 2024
- Link: <https://www.sciencedirect.com/science/article/abs/pii/S1359836824005821>
- What it shows and why it matters: Addresses a core scale-up issue (infiltrating nanoporous CNT networks) using in-situ interfacial polymerization; reports specific stiffness up to **142 N/tex** and tenacity **2.2 N/tex**, and demonstrates a **prototype roll-to-roll** apparatus for continuous processing—strong evidence for manufacturability beyond benchtop. [47]

### 15) Effective interlaminar toughening of CFRP laminate by extremely low loadings of monolayer graphene oxide

- Authors/organisation: Chongyang Gao[48] et al.
- Venue/type: Peer-reviewed paper (publisher preview via ResearchGate; paper in Polymer Composites[49])
- Publication date: Accepted 10 Oct 2024; journal issue year shown as 2025
- Link: [https://www.researchgate.net/publication/385425990\\_Effective\\_interlaminar\\_toughening\\_of\\_carbon\\_fiberepoxy\\_composite\\_laminates\\_by\\_extremely\\_low\\_loadings\\_of\\_monolayer\\_graphene\\_oxide](https://www.researchgate.net/publication/385425990_Effective_interlaminar_toughening_of_carbon_fiberepoxy_composite_laminates_by_extremely_low_loadings_of_monolayer_graphene_oxide)
- What it shows and why it matters: Uses an “ultrafine spraying” interlaminar method to distribute monolayer GO between CFRP plies; reports **Mode-I fracture toughness +140%** at extremely low GO loadings and frames this as a low-cost path with industrial scale-up potential—directly supporting the ART’s “large gains using familiar laminates/coatings” claim. [50]

### 16) Efficacy of carbon nanotube bucky paper for interlaminar damage sensing in composites and fibre-metal laminates

- Authors/organisation: Vinay Kumar[51] and Prabhat Agnihotri[52] et al.
- Venue/type: Peer-reviewed paper (publisher preview via ResearchGate; Polymer Composites)
- Publication date: Dec 2024 (ResearchGate metadata)
- Link: [https://www.researchgate.net/publication/386580108\\_Efficacy\\_of\\_carbon\\_nanotube\\_bucky](https://www.researchgate.net/publication/386580108_Efficacy_of_carbon_nanotube_bucky)

\_paper\_for\_interlaminar\_damage\_sensing\_in\_composites\_and\_fiber-metal\_laminates

- What it shows and why it matters: Demonstrates CNT bucky-paper interleaves for strain/damage sensing; reports sensor strain accuracy comparable to a commercial **120  $\Omega$  strain gauge** and shows delamination detection as a steep resistance rise across multiple laminate types including GLARE, supporting multi-material applicability. [53]

### 17) Self-sensing composites with damage mapping using 3D carbon fibre grid

- Authors/organisation: G. Jovarauskaite[54] et al.

- Venue/type: Peer-reviewed paper (Composites Part B: Engineering; journal entity already introduced)

- Publication date: 15 Apr 2025

- Link: <https://www.sciencedirect.com/science/article/abs/pii/S1359836825000721>

- What it shows and why it matters: Develops sandwich composites combining 3D carbon-fibre grids and CNT-modified conductive layers; maps damage area/size via **local electrical resistance deviation**, comparing sensitivity across **0.1–0.5 wt% CNT**—a concrete prototype of “electrically readable damage maps” for aerospace and wind blades. [55]

### 18) Galvorn Data Sheet

- Authors/organisation: DexMat[56]

- Venue/type: Vendor technical doc (data sheet)

- Publication date: Aug 2025

- Link: [https://dexmat.com/wp-content/uploads/Galvorn-Data-Sheet\\_20AUG2025.pdf](https://dexmat.com/wp-content/uploads/Galvorn-Data-Sheet_20AUG2025.pdf)

- What it shows and why it matters: Provides quantified properties for CNT fibre/yarn forms (e.g., conductivity, tensile strength, modulus, available lengths) and explicitly notes customers use CNT fibre tows for “electrodes, sensors, composites”; a sign that **CNT-based “engineered fabric” reinforcements** are already in product form factors, even if structural qualification remains application-specific. [57]

## 3. Maturity score (1–7) and reasoning

### A) Final maturity score: 4

### B) Evidence-to-rubric mapping

- **What evidence rules out levels 1–3 (the “lab principle only” region)**
- Multiple peer-reviewed studies demonstrate **functional laminate-level prototypes** that simultaneously deliver (i) mechanical delamination/toughening benefits and/or (ii) electrically enabled sensing/damage monitoring in representative composite architectures. Examples include PU/RGO interleaves with **Mode-I +170%** and shear strength gains in carbon/epoxy laminates, and monolayer GO interlaminar modification with **Mode-I +140%** improvements. [58]
- Embedded sensing is demonstrated with quantified localisation performance, e.g., ERT-based impact damage mapping with **~4.5% area error** in CNT-coated fibre sensing layers. [59]
- Industrially oriented integration paths are explicitly tested, such as using an **industrial CNT masterbatch** for interleaves and performing in-situ resistance measurements during fracture tests—moving beyond “principle shown” into “prototype in a manufacturing-relevant form factor”. [32]
- **Why the evidence supports level 4 (PoC) rather than level 5+**

- Level 4 requires a functional PoC that plausibly meets commercial requirements (functionality and viability for production). The dossier contains repeated PoCs for key claims:
  - **Structural repair/joint interface performance** with nano-integration demonstrated in a repair-relevant geometry (scarf patches) showing near-complete stiffness recovery. [28]
  - **Self-diagnostic / self-sensing** laminate concepts demonstrated under indentation/impact/delamination tests and correlated with DIC/tomography or resistance mapping. [60]
  - **Scale-up enablers** like dispersion QC via ML for CNT-resin systems and prototype continuous (roll-to-roll) processing for CNT yarn composites. [61]
- However, the sources do **not** provide strong, direct evidence that multiple well-capitalised actors are already competing with near-finished **production prototypes for structural aerospace/automotive primary parts**, nor do they show **increasing customer deliveries** of structural components at scale (levels 5–7). Instead, the evidence is dominated by lab-to-pilot demonstrations, methods papers, and enabling standards work. [62]
- A key “missing maturity” signal is that performance can be **highly formulation-dependent** and even negative in some conditions (e.g., the CNT masterbatch interleave at 0.6 wt% showing ~80% detrimental effect on Mode-I toughness). This kind of sensitivity indicates that robust process windows, qualification datasets, and production consistency are still being stabilised—more consistent with PoC than near-market production. [32]
- **What is still missing to justify the next higher level (5)**
- Public evidence of **production-prototype programmes** (e.g., automotive/aerospace supplier qualification campaigns, standardised test allowables, certified manufacturing routes) plus clear investment activity specific to **structural CNT/graphene-reinforced composite parts**, not only sensing concepts. [63]
- Demonstrated **field trials / service exposure** showing durability under environment (moisture, thermal cycling, fatigue spectrum loading) with quantified maintenance/inspection reductions enabled by embedded sensing. Current sources focus mostly on lab tests (DCB, impacts, cyclic bending rigs). [64]
- Clear evidence of **repeatable quality at scale** (batch-to-batch control, supplier specs, inline inspection deployment). There are strong “enablers” (ML dispersion QC; ISO characterisation/purity standards), but not yet a mature ecosystem of widely adopted industrial standards and audited supply chains for structural composites. [65]

### C) Sub-component maturity breakdown and aggregation

- **Interlaminar toughening with CNT/graphene interleaves (delamination resistance)**  
→ 4
- Evidence: large improvements in interlaminar fracture properties are demonstrated in laminate architectures (PU/RGO interleaves; GO ultrafine spraying) and a scalable industrial masterbatch route is tested, but results remain process-sensitive. [66]
- **Self-sensing / damage localisation via electrical resistance mapping** → 4

- Evidence: ERT-based impact damage localisation with quantified error; resistance-based shear damage evaluation; damage mapping in sandwich composites across CNT loadings. [67]
- **Scale-up enablers: dispersion QC + continuous processing → 4–5 (leaning 4)**
- Evidence: ML-based dispersion assessment suitable for in-line QC; roll-to-roll prototype processing for CNT yarn composites suggests manufacturability, but widespread industrial adoption isn't demonstrated in these sources. [61]
- **Standards / metrology / safety envelope (graphene/CNT characterisation and handling) → 3–4**
- Evidence: new ISO graphene characterisation work item and CNT impurity quantification methods; NIOSH sampling guidance. These are necessary underpinnings but don't alone demonstrate market readiness. [9]

**Aggregation to one score:** The ART's core functionality (lightweight structural reinforcement + self-sensing) is largely shared across variants; most critical elements cluster around mature PoC demonstrations with incomplete evidence of production scaling and field deployment. Therefore, the overall single score is set to **4**. [68]

## ART 07.051 Smart Thermal Materials for Energy-Efficient Heating & Cooling

### ART extraction

#### A) Primary capability the ART claims

- Retrofittable materials that **dynamically manage heat flow** (block, spread, store/release, or radiate heat) to reduce heating/cooling energy demand and improve thermal safety/comfort. [1]
- A **portfolio/suite approach**: layered insulations + coatings + thermal interface layers + embedded structures, increasingly coordinated with sensing/control (semi-passive to actively switchable). [2]
- **Peak load and temperature stabilisation** via latent thermal storage (phase-change cycling) and dynamic envelope behaviour (switchable insulation / “thermal valve” behaviour). [3]

#### B) Key sub-components / variants (sub-threads)

- **Switchable thermal resistance / “thermal valves”** (electrically or thermally triggered thermal conductivity switching; electrochemical thermal switches). [4]
- **Phase change materials (PCMs)** for load shifting/peak shaving in buildings and HVAC add-ons (ceiling tiles, wallboards, heat exchangers). [5]
- **Superinsulation**: vacuum insulation panels (VIPs) and their ageing/declared performance; thin high-R retrofits. [6]
- **Aerogel-based insulations** (blankets/composites) targeting thin, hydrophobic, high-temperature, mechanically robust insulation. [7]
- **Radiative cooling coatings/films** (passive daytime radiative cooling; durable, scalable paints/coatings; building field tests; appliance integration). [8]
- **Thermal interface materials (TIMs)** including phase-change TIMs for robust heat transfer at interfaces (electronics/modules; transferable concept to industrial thermal interface pads). [9]
- **Variable-emissivity (“smart radiative”) surfaces** (electrochromic IR modulation at large area form factors). [10]

#### C) Maturity indicators that would count as evidence

- **Measured performance vs baselines**: thermal conductivity switching ratios/widths, emissivity modulation ( $\Delta\epsilon$ ), sub-ambient cooling ( $\Delta T$ ), building energy savings (%), R-values/ $\lambda$ -values, cycle life, ageing drift. [11]
- **Durability and compliance evidence**: repeatable cycling, outdoor exposure stability, ageing/edge effects for VIPs, fire class ratings, standards-referenced testing. [12]
- **Field deployments / operational trials** (occupied building retrofits; long-term roof tests; appliance integration). [13]

- **Commercial product signals:** dated datasheets/brochures, “shipping option” features (e.g., factory-applied TIM), multiple vendors with comparable offerings. [14]
- **Roadmaps / programs / multi-country consortia** (evidence of sustained funded effort and standardisation pathways). [15]

## 2. Evidence (10–20 recent, reliable sources)

### 1) **Techno-Economic Analysis of Dynamic Building Envelopes Comprising Phase Change Materials and Switchable Insulations (Preprint)**

- Authors/Org: National Renewable Energy Laboratory[16]
- Venue/type: Government lab conference paper / preprint
- Publication date: **January 2023**
- Link: <https://docs.nrel.gov/docs/fy23osti/82623.pdf>
- Reports a techno-economic framing for **dynamic envelopes combining PCMs and “switchable” insulation** to better exploit ambient/free heating-cooling and improve load shifting, directly supporting the ART’s “thermal valve + thermal storage” plausibility at building scale. [17]

### 2) **Retrofittable Thermal Switches for Dynamic Building Envelopes Integrated with Thermal Energy Storage: Preprint**

- Authors/Org: U.S. Department of Energy Building Technologies Office[18] + National Renewable Energy Laboratory[16]
- Venue/type: Government lab conference paper / preprint
- Publication date: **October 2024** (presented Aug 2024)
- Link: <https://docs.nrel.gov/docs/fy25osti/89100.pdf>
- Directly targets **retrofittable “thermal switch” concepts** integrated with latent storage (PCMs), which is a close match to the ART’s suite idea (insulation ↔ heat flow switching + storage). [19]

### 3) **Technology Strategy Assessment – Thermal Energy Storage**

- Authors/Org: U.S. Department of Energy[20]
- Venue/type: Authoritative government strategy/report
- Publication date: **July 2023**
- Link: <https://www.energy.gov/sites/default/files/2023-07/Technology%20Strategy%20Assessment%20-%20Thermal%20Energy%20Storage.pdf>
- Positions TES (including **latent storage**) as a pathway to reduce peak demand and enable flexibility in buildings, supporting the ART’s value proposition and signalling sustained programme interest. [21]

### 4) **Energy Storage TCP Annual Report 2023** (Task 40: Compact Thermal Energy Storage)

- Authors/Org: International Energy Agency[22] (Energy Storage TCP)
- Venue/type: Authoritative international programme report
- Publication date: **June 2024** (report release shown)
- Link: [https://iea-es.org/wp-content/uploads/public/ES\\_TCP\\_Annual\\_Report\\_2023.pdf](https://iea-es.org/wp-content/uploads/public/ES_TCP_Annual_Report_2023.pdf)
- Documents a multi-country collaboration focused on **characterisation, degradation, and state-of-charge determination** for compact TES (PCM/TCM), mapping strongly to the ART’s constraints around cycling drift and monitoring/control. [23]

**5) A phase change material (PCM) based novel retrofitting approach in the air conditioning system to reduce building energy demand**

- Authors/Org: Rahul Kumar Sharma[24] et al.
- Venue/type: Peer-reviewed paper (Applied Thermal Engineering)
- Publication date: **1 February 2024**
- Link: <https://www.sciencedirect.com/science/article/abs/pii/S1359431123019014>
- Demonstrates an HVAC retrofit using a **PCM heat-exchanger** approach and reports a **peak energy saving of ~12%** in the studied configuration—evidence that “heat storage without bulky tanks” can work in conventional systems. [25]

**6) Energy performance of an operational government building retrofitted with ceiling phase change material tiles in a mixed-humid climate**

- Authors/Org: Sajith Wijesuriya[26] et al.
- Venue/type: Peer-reviewed paper (Energy and Buildings)
- Publication date: **1 March 2025**
- Link: <https://www.sciencedirect.com/science/article/abs/pii/S037877882500043X>
- Provides rare **operational-building retrofit evidence** for PCM ceiling tiles, addressing maturity indicators beyond lab tests (real schedules/loads, practical retrofit constraints). [27]

**7) From lab to building: Real-world integration of phase change materials for comfort, energy, and flexibility**

- Authors/Org: Shady Attia[28] et al.
- Venue/type: Peer-reviewed paper (Energy and Buildings)
- Publication date: **1 February 2026**
- Link: <https://orbi.uliege.be/handle/2268/338044>
- Synthesises evidence from **eight full-scale monitored buildings** (explicitly framed at **TRL 6–9**), supporting that PCM retrofits are beyond theory and increasingly evaluated in real deployments. [29]

**8) High-performance solid-state electrochemical thermal switches with earth-abundant cerium oxide**

- Authors/Org: Ahnong Jeong[30] et al. (Hokkaido University[31]; The University of Tokyo[32])
- Venue/type: Peer-reviewed paper (Science Advances)
- Publication date: **January 2025**
- Link: <https://pmc.ncbi.nlm.nih.gov/articles/PMC11691636/>
- Demonstrates an electrically switched thermal device with  **$\kappa$  changing from ~2.2 to ~12.5 W/m·K** (on/off ratio **5.8**) over **100 cycles**, supporting feasibility of “thermal valves” albeit currently in specialised device form factors. [33]

**9) Observation of solid-state bidirectional thermal conductivity switching in antiferroelectric lead zirconate (PbZrO<sub>3</sub>)**

- Authors/Org: Kiumars Aryana[34] et al.
- Venue/type: Peer-reviewed paper (Nature Communications)
- Publication date: **23 March 2022**
- Link: <https://www.nature.com/articles/s41467-022-29023-y>
- Reports solid-state thermal conductivity modulation including an **~10% decrease under electrical bias** and **~25% increase under heating**, reinforcing plausibility of stimulus-

responsive “thermal switching” materials while highlighting early-stage integration challenges. [35]

#### 10) Flexible and large-area electrochromic infrared devices with superior modulation functionality

- Authors/Org: Zongtao Zhang[36] et al.

- Venue/type: Peer-reviewed paper (Chemical Engineering Journal)

- Publication date: **15 January 2025**

- Link:

<https://www.sciencedirect.com/science/article/abs/pii/S1385894724104445>

- Shows large-area-compatible IR electrochromic devices with emissivity tuning ( $\Delta\epsilon \sim 0.56$  in **8–14  $\mu\text{m}$** ) and a reported **radiative temperature modulation of  $\sim 10.9^\circ\text{C}$** , supporting the ART’s “tunable radiative loss” pathway (still prototype maturity). [10]

#### 11) Analysis of the thermal and energy saving performance of the concrete roof with radiative cooling coating

- Authors/Org: Qingdong Xuan[37] et al.

- Venue/type: Peer-reviewed paper (Journal of Building Engineering)

- Publication date: **15 July 2025**

- Link:

<https://www.sciencedirect.com/science/article/abs/pii/S2352710225008150>

- Long-term **field tests on an in-service office building** report up to **20% electricity reduction** under identical A/C settings and large roof surface temperature reduction, directly supporting maturity via real-world building evidence. [38]

#### 12) Daytime radiative cooling coating for cooling energy efficiency of conventional air conditioners

- Authors/Org: Zheng Yang[39] et al.

- Venue/type: Peer-reviewed paper (Applied Thermal Engineering)

- Publication date: **15 February 2025**

- Link:

<https://www.sciencedirect.com/science/article/abs/pii/S1359431124027285>

- Integrates a passive sub-ambient radiative cooling coating into **real A/C external units** and reports improved cooling energy efficiencies (e.g.,  **$\sim 12\text{--}13\%$**  depending on system type), evidencing “retrofit coating” viability in conventional equipment. [40]

#### 13) Water-Based Hydrophobic Paints for Daytime Radiative Cooling

- Authors/Org: Abdulrahman K. Aljwirah[41] et al.

- Venue/type: Peer-reviewed paper (ACS Applied Materials & Interfaces)

- Publication date: **21 May 2025**

- Link:

[https://engineering.purdue.edu/NANOENERGY/publications/Aljwirah\\_ACS%20AMI\\_2025.pdf](https://engineering.purdue.edu/NANOENERGY/publications/Aljwirah_ACS%20AMI_2025.pdf)

- Demonstrates **water-based, low-VOC** radiative-cooling paint formulations with reported **daytime sub-ambient cooling ( $\sim 2.7^\circ\text{C}$ )**, addressing manufacturability/safety barriers that often block scaling for coatings. [42]

#### 14) Vacuum Insulation Panel: Evaluation of Declared Thermal Conductivity Value and Implications for Building Energy

- Authors/Org: Fred Edmond Bofo[43] et al.
- Venue/type: Peer-reviewed paper (Energies, open access)
- Publication date: **7 August 2023**
- Link: <https://www.mdpi.com/1996-1073/16/15/5841>
- Quantifies VIP ageing/declared performance: reports mean centre-of-panel  $\lambda$  around **0.0042 W/(m·K)** and shows how different declared/aged  $\lambda$  metrics materially affect energy modelling outcomes—key for long-term reliability claims. [44]

#### 15) **va-Q-vip – Technical Data Sheet**

- Authors/Org: va-Q-tec[45]
- Venue/type: Vendor technical doc (dated datasheet)
- Publication date: **7 February 2023**
- Link: [https://www.va-q-tec.com/wp-content/uploads/pimcore-2/230207\\_va-Q-vip\\_English.pdf](https://www.va-q-tec.com/wp-content/uploads/pimcore-2/230207_va-Q-vip_English.pdf)
- Provides productised VIP metrics (e.g., initial thermal conductivity at delivery  $\leq$  **0.0050 W/(m·K)** at 10 °C; stated lifetime “up to 60 years” depending on usage), supporting that VIPs are already market-delivered superinsulation components. [46]

#### 16) **Panasonic ADVANC-R® Vacuum Insulation Panel (VIP) – Product Brochure**

- Authors/Org: Panasonic[47]
- Venue/type: Vendor technical doc (product brochure with standards references)
- Publication date: **August 2023**
- Link: <https://www.holcimelevate.com/content/dam/elevateamericas/migrated-document/us/en/60/605976.pdf>
- Describes a building-focused VIP product with centre-of-panel **R-value 66** (reported) and **Class A** flame/smoke rating, indicating commercial offerings exist that fit retrofit constraints (thin, high-R). [48]

#### 17) **Spaceloft® Subsea insulation system – Product data sheet (Rev 5.2)**

- Authors/Org: Aspen Aerogels[49]
- Venue/type: Vendor technical doc (dated revision/year)
- Publication date: **2024** (©2024; Rev 5.2)
- Link: [https://www.aerogel.com/wp-content/uploads/2025/01/Spaceloft-Subsea-datasheet-updated-V2\\_2024\\_v5.2.pdf](https://www.aerogel.com/wp-content/uploads/2025/01/Spaceloft-Subsea-datasheet-updated-V2_2024_v5.2.pdf)
- Shows mature, field-deployed aerogel insulation with thermal conductivity values on the order of **~13–19 mW/(m·K)** across temperatures and claims **>1 million km of pipelines insulated**, indicating substantial real-world deployment (albeit in industrial subsea contexts). [50]

#### 18) **ArmaGel HT – Technical Datasheet**

- Authors/Org: Armacell[51]
- Venue/type: Vendor technical doc (dated datasheet)
- Publication date: **9 January 2026**
- Link: <https://www.armacell.com/sites/default/files/2026/01/09/ArmaGel%20HT%20-%20Technical%20Datasheet%20-%20en-US.pdf>
- Documents a commercial aerogel blanket rated for **up to 650 °C** and compliance to an insulation material standard (ASTM C1728), aligning with the ART’s “thin superinsulation within existing workflows” and durability/fire constraints. [52]

### 19) Fabrication of flexible silica aerogel composite blankets from an aqueous fumed silica-based slurry

- Authors/Org: Shunyao Zhang[53] et al.
- Venue/type: Peer-reviewed paper (Science China Materials)
- Publication date: **5 March 2024**
- Link: <https://link.springer.com/article/10.1007/s40843-023-2787-5>
- Demonstrates a lower-complexity route (ambient drying + slurry impregnation/roller pressing) to flexible aerogel blankets and reports **thermal conductivity ~0.046 W/m·K** (monolith) and **~0.054 W/m·K at 800 °C** (optimised blanket), supporting manufacturability improvements. [54]

### 20) Hydrophobic phenolic/silica aerogel composites with high fire safety and strength for efficient thermal insulation

- Authors/Org: Yonghua Wang[55] et al.
- Venue/type: Peer-reviewed paper (RSC Advances; open via PMC)
- Publication date: **5 November 2025**
- Link: <https://pmc.ncbi.nlm.nih.gov/articles/PMC12587478/>
- Reports an aerogel composite targeting key constraints (moisture + mechanical + high-temperature stability), including **very low reported thermal conductivity (~0.021 W/m·K)** and strong hydrophobicity, addressing durability/fire-performance bottlenecks relevant to building-scale materials. [56]

## 3. Maturity score (1–7) and reasoning

### A) Final maturity score: 5

### B) Why this rules out lower levels, and what blocks a higher level

A score below **4** is ruled out because multiple elements of the ART are already **beyond lab prototype**: there are **operational-building retrofits** using PCMs (not just test cells), and there are **long-term field tests** of radiative cooling coatings on real buildings and conventional A/C equipment with quantified energy/performance impacts. [13]

A score below **5** is also difficult to justify because several sub-threads already have **market-delivered, dated technical documentation** (VIPs and aerogel blanket products with standardised properties and installation/ratings), and multiple well-capitalised industrial actors exist in these categories—indicating the space is already in production-prototype or product phases for parts of the suite. [57]

A score of **6** for the ART *as a whole* is not supported yet because the “smart thermal materials” concept in the prompt is explicitly a **coordinated suite** including **dynamic switching (“thermal valves”)** and sensor/control-aware operation at scale; the strongest thermal-switch evidence remains in specialised device demonstrations (e.g., electrochemical  $\kappa$ -switching with defined cycling limits) rather than widely deployed building/appliance-grade products with standardised durability + cost/performance-at-scale validation. [4]

A score of **7** would require evidence that competing *integrated* solutions are being delivered broadly with rising demand and largely internally financed growth across the whole suite; the evidence base here shows a mixed landscape: **superinsulation and aerogel blankets are**

**strongly commercial**, but **dynamic thermal switching and large-area variable-emissivity control** remain closer to R&D/prototype stages. [58]

### C) Sub-scores (bundle components) and aggregation approach

Because the ART bundles materially different mechanisms and markets (envelope superinsulation vs latent storage vs dynamic switching vs radiative coatings), an **average-based** assessment is most defensible.

- **Superinsulation (VIPs) → 6**
- Evidence: commercial VIP datasheets with quantified  $\lambda/R$  and building-target packaging/fire ratings. [59]
- **Aerogel insulation blankets → 6**
- Evidence: vendor datasheets showing high-temperature aerogel blanket products; also a vendor-documented large deployment footprint in industrial contexts. [60]
- **PCM-based thermal storage in building retrofits → 5–6**
- Evidence: operational building retrofit studies and synthesis of full-scale monitored buildings at TRLs 6–9; still not uniformly mainstream. [61]
- **Radiative cooling coatings/films → 4–5**
- Evidence: long-term in-service building roof field tests and appliance integration with quantified energy-efficiency improvements; still limited proof of mass-market standardisation/durability across many climates and suppliers. [8]
- **Dynamic “thermal valves” / thermal conductivity switching materials → 3–4**
- Evidence: peer-reviewed demonstrations of  $\kappa$ -switching (electrochemical and ferroic systems) with cycling evidence, but not yet broadly packaged for commodity building/HVAC retrofits. [62]
- **Large-area variable-emissivity IR control (electrochromic IR devices) → 4**
- Evidence: large-area-compatible prototypes with strong  $\Delta\epsilon$  and durability claims in a peer-reviewed venue, but not yet established as a scaled building product category. [10]

**Aggregation:** Averaging the above sub-scores yields an overall maturity around the **mid-5 range**, and the bundle’s “smart coordinated suite” character (dynamic switching + monitoring + scalable durability) is not yet consistently at product-delivery scale, so the consolidated score is set to **5**. [63]

## ART 07.052 Rare-Earth-Free Magnets for Sustainable Motors

### . ART extraction

- **Primary capability (what the ART claims)**
- Rare-earth-free **permanent magnets** that can be used in efficient electric motors (and related rotating machines) while reducing dependence on Nd-Fe-B supply chains and associated price/availability volatility. [1]
- A **practical family** of magnet materials spanning performance tiers (e.g., “good-enough” torque density via motor/topology optimisation; higher-temperature stability; lower cost; improved corrosion resistance), with industrially interpretable specifications. [2]
- **Manufacturability via familiar routes** (powders → sintered blocks, bonded shapes, additively manufactured parts) to minimise retooling and accelerate adoption. [3]
- **Key sub-threads / variants**
- **Ferrite** (Sr/Ba hexaferrite) magnets + motor topologies that compensate for lower remanence (e.g., spoke rotors, PM-assisted SynRM). [4]

- **MnBi** magnets (notable for coercivity increasing with temperature) in bonded and bulk/warm-sintered forms; microstructure/grain-boundary engineering to reduce coercivity loss upon densification. [5]
- **MnAl ( $L1_0$  /  $\tau$ -MnAl, often Mn–Al–C)** magnets; twin suppression, grain/particle size control, texture development; emerging manufacturing (e.g., LPBF). [6]
- **Iron nitride ( $\alpha$ "-Fe<sub>16</sub>N<sub>2</sub>)** magnets; low-temperature consolidation and alignment/bonding strategies to address metastable phase decomposition. [7]
- **FeNi (tetrataenite  $L1_0$ -FeNi)** and FeNi-inspired microstructures; thin-film synthesis routes; contested bulk-casting claims and subsequent corrections/retractions. [8]
- **System-level “compensation”**: geometry, thermal management, demagnetisation-robust designs, and control strategies that allow lower-Br magnets to meet application specs. [9]
- **Maturity indicators that would count as strong evidence**
- **Materials performance**: measured coercivity ( $H_c/H_{cj}$ ), remanence ( $Br/M_r$ ), and/or energy product ( $(BH)_{max}$ ) at relevant temperatures; evidence of stability against demagnetisation and cycling. [10]
- **Process viability at scale**: demonstrable densification/texture routes (SPS, high-pressure compaction, bonded magnets, AM) that preserve critical phases and reduce defect rates. [11]
- **Prototype rotating machine results**: traction/industrial motor prototypes hitting meaningful output/efficiency and showing demagnetisation robustness. [12]
- **Field trials & reliability**: fatigue/endurance testing, operation in real industrial equipment, and repeatable quality profiles. [13]
- **Scaling signals**: participation of major magnet/motor manufacturers, funded multi-partner programmes, patents with concrete engineering detail, and movement toward mass production. [14]

## 2. Evidence (10–20 recent, reliable sources)

### 1) Production and characterization of compacted Fe<sub>16</sub>N<sub>2</sub> permanent magnets

- **Authors/Org**: Nilay Gunduz Akdogan[15] et al.
- **Type/Venue**: Peer-reviewed paper, *Acta Materialia*
- **Date**: Aug 2022
- **Link**: <https://doi.org/10.1016/j.actamat.2022.118064>
- **Why it matters (concise)**: Demonstrates rare-earth-free Fe<sub>16</sub>N<sub>2</sub> compacts made by **cold compaction (~1 GPa) plus annealing under higher pressure** to reach ~80% density while preserving Fe<sub>16</sub>N<sub>2</sub>, directly addressing manufacturability of metastable iron-nitride magnets. [16]

### 2) Production of Rare-Earth-Free Iron Nitride Magnets ( $\alpha$ "-Fe<sub>16</sub>N<sub>2</sub>)

- **Authors/Org**: Tetsuji Saito[17] et al.
- **Type/Venue**: Peer-reviewed paper, *Metals* (MDPI)
- **Date**: Jun 2024 (issue-dated)
- **Link**: <https://www.mdpi.com/2075-4701/14/6/734>
- **Why it matters (concise)**: Shows **low-temperature SPS/SPS-DC consolidation (373–573 K)** of Fe-N powders into magnets and reports measurable properties (e.g., saturation

magnetisation  $\sim 1.07$  T and coercivity  $\sim 0.20$  MA/m at 373 K for an SPS-DC sample), supporting plausibility but also highlighting temperature-stability constraints. [18]

### 3) Microstructural and Magnetic Evolution of $\alpha$ "-Fe<sub>16</sub>N<sub>2</sub> Bulk Magnets Consolidated by Spark Plasma Sintering

- **Authors/Org:** Marian Grigoras[19] et al.
- **Type/Venue:** Peer-reviewed paper, *Crystals* (MDPI)
- **Date:** Nov 2025
- **Link:** <https://doi.org/10.3390/cryst15110969>
- **Why it matters (concise):** Systematically maps SPS temperature/pressure trade-offs, reporting  **$\sim 80\%$  theoretical density**,  $M_s \sim 230$  A·m<sup>2</sup>/kg, and coercivity up to  $\sim 86.5$  kA/m under optimised conditions—useful evidence for process windows and remaining gaps to reach dense, high-(BH)<sub>max</sub> magnets. [20]

### 4) US20240047102A1 — Anisotropic iron nitride permanent magnets

- **Authors/Org:** Niron Magnetics, Inc.[21]
- **Type/Venue:** **Patent** (treat cautiously; engineering detail present)
- **Date:** Feb 2024
- **Link:** <https://patents.google.com/patent/US20240047102A1/en>
- **Why it matters (concise):** Claims concrete process concepts for **alignment and bonding** of iron-nitride nanoparticles (e.g., XRD intensity-ratio criteria, target squareness thresholds, and a method sketch with intrinsic coercivity ranges), indicating an industry push toward manufacturable rare-earth-free bonded magnets. [22]

### 5) Fabrication of L1<sub>0</sub>-ordered FeNi films by denitriding FeNiN(001) and FeNiN(110) films

- **Authors/Org:** Keita Ito[23] et al.
- **Type/Venue:** Peer-reviewed paper, *Journal of Alloys and Compounds*
- **Date:** Jun 2023
- **Link:** <https://doi.org/10.1016/j.jallcom.2023.169450>
- **Why it matters (concise):** Demonstrates a **denitridation route** to L1<sub>0</sub>-FeNi thin films and reports an FeNi long-range order parameter  **$S \approx 0.60$**  with  **$K_u \approx 0.55$  MJ/m<sup>3</sup>** for (110) films—strong plausibility evidence for anisotropy engineering, but still thin-film-limited for motor magnets. [24]

### 6) Origin of the high coercivity in FeNi inspired magnets

- **Authors/Org:** A. Hernando[25] et al.
- **Type/Venue:** Peer-reviewed paper, *Scientific Reports*
- **Date:** Jan 2026
- **Link:** <https://www.nature.com/articles/s41598-026-36990-5>
- **Why it matters (concise):** Reports FeNi-based microwires with **room-temperature coercivity  $\sim 440$  Oe** and argues the coercivity arises from microstructure/shape isolation rather than requiring L1<sub>0</sub>-FeNi—useful for plausibility (alternative hard-magnet pathways) but indicates performance still far below NdFeB-class levels. [26]

### 7) Direct Formation of Hard-Magnetic Tetrataenite in Bulk Alloy Castings (*retracted; include as contested evidence*)

- **Authors/Org:** Y. P. Ivanov[27] et al.
- **Type/Venue:** Peer-reviewed paper (**retracted**), *Advanced Science*
- **Date:** 2022 (received Jul 2022; retraction noted)

- **Link:** <https://pmc.ncbi.nlm.nih.gov/articles/PMC9811435/>
- **Why it matters (concise):** Initially claimed bulk tetrataenite formation via casting at much higher cooling rates than meteorites, which—if true—would have been a major maturity jump; the paper is explicitly marked **retracted**, underscoring the difficulty of reproducible bulk FeNi hard-magnet synthesis. [28]

#### 8) Reinterpretation of Report of Tetrataenite in Bulk Alloy Castings

- **Authors/Org:** Owain S. Houghton[29] et al.
- **Type/Venue:** Peer-reviewed paper, *Advanced Science* (recorded in PubMed)
- **Date:** Epub Dec 2024 / Jan 2025 issue
- **Link:** <https://pubmed.ncbi.nlm.nih.gov/39680740/>
- **Why it matters (concise):** Provides the corrective analysis: diffraction peaks and electron-diffraction reflections previously attributed to tetrataenite were instead linked to **(Fe,Ni)<sub>3</sub>P and oxidation**, and magnetic hysteresis showed **no expected high-coercivity regions**, lowering near-term maturity expectations for bulk FeNi magnets. [30]

#### 9) Roadmap towards optimal magnetic properties in L1<sub>0</sub>-MnAl permanent magnets

- **Authors/Org:** Yuxiao Jia[31] et al.
- **Type/Venue:** Peer-reviewed paper, *Acta Materialia*
- **Date:** Feb 2023
- **Link:** <https://doi.org/10.1016/j.actamat.2022.118654>
- **Why it matters (concise):** Proposes a manufacturing-relevant route to higher MnAl performance by suppressing twins via **grain/particle size < ~300 nm**, with analysis suggesting optimal coercivity at **~50–200 nm** and a pathway to higher texture (system-level readiness via predictable microstructure control). [32]

#### 10) Additive manufacturing of Mn–Al permanent magnets via laser powder bed fusion

- **Authors/Org:** (as cited in journal preview; author list not foregrounded in the abstract page)
- **Type/Venue:** Peer-reviewed paper, *Materialia* (Elsevier)
- **Date:** 2024
- **Link:** <https://www.sciencedirect.com/science/article/abs/pii/S2589152923003058>
- **Why it matters (concise):** Demonstrates LPBF processing that converts  $\varepsilon \rightarrow \tau$  with annealing and reports measurable properties (e.g.,  $H_{ci} \approx 129$  kA/m and  $(BH)_{max} \approx 7.2$  kJ/m<sup>3</sup> along the print direction), providing plausibility evidence for **shape-flexible manufacturing** even though performance remains low vs mature magnet classes. [33]

#### 11) Engineering microstructure to improve coercivity of bulk MnBi magnet

- **Authors/Org:** Wei Tang[34] et al.
- **Type/Venue:** Peer-reviewed paper, *Journal of Magnetism and Magnetic Materials*
- **Date:** Sep 2022
- **Link:** <https://doi.org/10.1016/j.jmmm.2022.169912>
- **Why it matters (concise):** Addresses a core scaling blocker (coercivity collapse on densification): reports  $H_{cj}$  loss reduced **from ~70% to ~15%** by engineering non-magnetic grain-boundary phases, achieving **(BH)<sub>max</sub> ≈ 8.9 MGOe** in warm-sintered bulk MnBi—directly relevant to motor-grade material viability. [35]

#### 12) CMI scientists develop rare earth free magnet for use in industrial motors

- **Authors/Org:** Ames Laboratory[36] (with industry partners)
- **Type/Venue:** Authoritative national-lab project update (not peer-reviewed; used for maturity

signal)

- **Date:** May 2025

- **Link:** <https://www.ameslab.gov/news/cmi-scientists-develop-rare-earth-free-magnet-for-use-in-industrial-motors>

- **Why it matters (concise):** Reports a **MnBi bonded magnet** with high-temperature robustness (coercivity reportedly nearly doubles over a +100°C increase) and notes collaboration with an industrial partner testing the magnet in an **industrial pump motor**, progressing to **fatigue tests**—a meaningful step past lab coupon results. [37]

### 13) Ames Lab Technology Wins R&D 100 Award

- **Authors/Org:** Critical Materials Innovation Hub[38] / Ames Lab

- **Type/Venue:** Award/recognition notice (supporting maturity signal)

- **Date:** Aug 2025

- **Link:** <https://www.ameslab.gov/news/ames-lab-technology-wins-r-d-100-award>

- **Why it matters (concise):** Confirms external recognition for MnBi-based rare-earth-free permanent magnets and reiterates the high-temperature behavioural advantage (temperature-positive coercivity trend), suggesting progress toward application-relevant performance targets. [39]

### 14) Output exceeding 100 kW applicable for traction motors for BEVs and PHEVs verified on actual ferrite magnet motor

- **Authors/Org:** Proterial, Ltd.[40]

- **Type/Venue:** Industry technical release with measured prototype data (manufacturer doc)

- **Date:** Jul 2023

- **Link:** <https://www.proterial.com/e/press/2023/pdf/20230724en.pdf>

- **Why it matters (concise):** States that a high-performance ferrite magnet (NMFTM-15) was used to **build and evaluate an actual traction-motor prototype**, verifying **>100 kW output** (reported 102 kW measured) at up to **15,000 rpm**, showing rare-earth-free magnets can reach traction-relevant power in practice (with design trade-offs). [41]

### 15) Experimental Validation of a Spoke Type Ferrite Permanent Magnet Machine Design for Heavy-Duty Traction Applications

- **Authors/Org:** Marcelo D. Silva[42] et al.; affiliations include Uppsala University[43], Scania CV AB[44], Alstom[45]

- **Type/Venue:** Peer-reviewed paper, *IET Electric Power Applications* (open access)

- **Date:** Accepted Nov 2025 (received Apr 2025)

- **Link:** <https://ietresearch.onlinelibrary.wiley.com/doi/10.1049/elp2.70133> (also mirrored PDF: <https://uu.diva-portal.org/smash/get/diva2:1950228/FULLTEXT01.pdf>)

- **Why it matters (concise):** Presents optimisation integrating demagnetisation and mechanical constraints and reports a **built and tested ferrite-PM spoke motor** intended to directly substitute a rare-earth motor of the same outer volume, with experimental results indicating demagnetisation resilience and **higher efficiency in field-weakening** than the REE baseline. [46]

### 16) Design, analysis and experimental evaluation of a novel high-speed high-power ferrite IPM machine for traction applications

- **Authors/Org:** (University of Sheffield collaboration; paper notes Innovate UK support)

- **Type/Venue:** Technical conference paper (measured prototype results)

- **Date:** 2022

- **Link:** [https://eprints.whiterose.ac.uk/id/eprint/192512/1/ECCE\\_conference-template\\_Khoa\\_Kais\\_GG\\_V3\\_Good.pdf](https://eprints.whiterose.ac.uk/id/eprint/192512/1/ECCE_conference-template_Khoa_Kais_GG_V3_Good.pdf)

- **Why it matters (concise):** Reports an **80 kW** ferrite IPM traction prototype (up to **12,000 rpm**) with measured vs FEA agreement and a stated **maximum efficiency of 97%**, supporting the “system-level compensation” thesis for rare-earth-free magnets in high-performance machines. [47]

#### 17) Sustainable ferrite permanent magnet fabrication: Recycling steel scale into high-performance strontium hexaferrite magnet

- **Authors/Org:** Kürşat İcin[48] et al.

- **Type/Venue:** Peer-reviewed paper, *Journal of the Indian Chemical Society*

- **Date:** Nov 2025

- **Link:** <https://doi.org/10.1016/j.jics.2025.102163>

- **Why it matters (concise):** Demonstrates a recycling-based ferrite supply route (steel scale +  $\text{SrCO}_3$ ) and reports magnetic properties including  **$H_c \approx 5526.6 \text{ Oe}$** ,  $M_r \approx 35.9 \text{ emu/g}$ ,  $M_s \approx 69.1 \text{ emu/g}$ , supporting plausibility of lower-impact manufacturing for scalable rare-earth-free magnets. [49]

#### 18) Emerging magnetic materials for electric vehicle drive motors

- **Authors/Org:** Christopher L. Rom[50] et al., National Renewable Energy Laboratory[51]

- **Type/Venue:** Authoritative review/roadmap-style article, *MRS Bulletin* (via NREL report PDF)

- **Date:** Jul 2024

- **Link:** <https://docs.nrel.gov/docs/fy24osti/88583.pdf>

- **Why it matters (concise):** Provides an expert synthesis of why many rare-earth-free candidates are **temperature-/process-sensitive** and argues that advances in **low-temperature synthesis/processing** are pivotal to commercialising alternatives beyond rare-earth magnets—directly supporting plausibility constraints and maturity bottlenecks. [52]

#### 19) Periodic Reporting (REFMAG): “Bulk rare earth free permanent magnets” (Horizon Europe project)

- **Authors/Org:** European Commission[53] (CORDIS project reporting)

- **Type/Venue:** Government/consortium programme evidence (multi-partner R&D)

- **Date:** Feb 2024 (reporting page)

- **Link:** <https://cordis.europa.eu/project/id/101069203/reporting>

- **Why it matters (concise):** Confirms an active EU-funded programme explicitly targeting **bulk rare-earth-free permanent magnets**, indicating geographically diverse investment and structured scaling pathways beyond single-lab demonstrations. [54]

#### 20) U.S. Department of Energy Critical Materials Assessment (2023)

- **Authors/Org:** U.S. Department of Energy[55]

- **Type/Venue:** Government assessment/roadmap context (supply-risk driver)

- **Date:** May 2023 (file-dated)

- **Link:** <https://www.energy.gov/sites/default/files/2023-05/2023-critical-materials-assessment.pdf>

- **Why it matters (concise):** Establishes the broader policy/industrial driver: criticality of materials and supply-chain risk as an explicit constraint on clean-energy deployment, strengthening the economic plausibility case for rare-earth-free magnet alternatives even if they require system redesign. [56]

### 3. Maturity score (1–7) and reasoning

#### A) Final maturity score: 4

#### B) Why level 4 fits (mapping evidence → rubric)

- **What rules out levels 1–3 (i.e., why this is beyond “principle only” or “lab-prototype only”)**
- There is direct, application-context evidence of **functional motor prototypes** using rare-earth-free permanent magnets, including an established manufacturer reporting an **actual ferrite-magnet traction motor prototype** with **measured ~102 kW output** (traction-relevant scale). [\[41\]](#)
- Peer-reviewed experimental work shows **design + build + test** of rare-earth-free (ferrite) traction machines with strong efficiency claims and validated modelling/measurement agreement (e.g., **80 kW prototype**, stated **97% max efficiency**). [\[47\]](#)
- For non-ferrite alternatives, there is peer-reviewed progress on **manufacturing blockers** (e.g., MnBi bulk magnet densification preserving coercivity, with reported reduction of H<sub>cj</sub> loss from ~70% to ~15% and (BH)<sub>max</sub> ≈ 8.9 MGOe). [\[35\]](#)
- There is at least one credible signal of **industrial trial context** for MnBi bonded magnets (industrial pump motor testing progressing to fatigue testing), consistent with proof-of-concept use in a real machine environment. [\[57\]](#)

Taken together, these exceed “lab principle verified” and “lab prototype exists” because they include **system-level prototypes** and (in at least one case) **measured performance** at meaningful scale. [\[58\]](#)

- **What is still missing for level 5 (why not higher)**
- The evidence set does **not** consistently show that multiple rare-earth-free magnet chemistries (beyond ferrites) have reached production-prototype maturity with clearly disclosed **repeatable manufacturing yields, cost curves, and lifetime/quality metrics** at industrial scale. [\[59\]](#)
- Some of the most “NdFeB-replacement-aspirational” candidates have strong **scientific plausibility** but remain constrained by processing/phase-stability challenges (e.g., iron-nitride low-temperature consolidation constraints; FeNi tetrataenite bulk formation controversies), which is inconsistent with “production prototype in finishing phase.” [\[60\]](#)
- There is limited public evidence (within the strict 4-year window and using primarily technical sources) of **shipping products in increasing amounts** for these new rare-earth-free high-performance magnet families (rubric levels 6–7). [\[61\]](#)

#### C) Sub-component maturity snapshot and aggregation

- **Ferrite magnets + compensating motor topologies (spoke / PM-assisted SynRM / flux concentration) → 5 (upper-4 to 5)**
- Justification: multiple sources show traction-relevant prototypes and experimental validation, including manufacturer-reported **>100 kW** measured prototype results and peer-reviewed prototype testing/validation. [\[12\]](#)
- **MnBi permanent magnets for motor applications (bonded + bulk/warm-sintered) → 4**

- Justification: peer-reviewed work resolves a key manufacturing blocker (coercivity preservation in bulk) and credible national-lab reporting indicates early machine trials and fatigue testing, consistent with proof-of-concept in a relevant system. [5]
- **MnAl (L1<sub>0</sub>-MnAl) magnets → 3**
- Justification: strong materials roadmap and emerging manufacturing demonstrations exist (e.g., LPBF experiments), but reported energy products are still low in current demonstrations and broad production viability remains unproven. [6]
- **Iron nitride ( $\alpha$ "-Fe<sub>16</sub>N<sub>2</sub>) magnets → 3**
- Justification: multiple experimental papers show low-temperature densification routes and measured magnetic properties; patent activity indicates engineering direction, but compacts remain well short of dense, high-coercivity, high-(BH)max industrial magnets. [62]
- **FeNi tetrataenite / FeNi-inspired hard magnets → 2**
- Justification: thin-film anisotropy progress is real, but bulk manufacturing remains highly challenging; a recent high-profile bulk-casting claim was **retracted** and subsequent analysis supports that tetrataenite was not present, indicating the field is still in an early validation phase for bulk motor magnets. [63]

**Aggregation rationale to one score:** Because the ART explicitly describes a **family** spanning tiers (and the maturity differs strongly by chemistry and application), a simple average would under-represent the near-market ferrite pathway while over-representing very early-stage FeNi. The practical “whole-ART” readiness is best represented as **level 4**: at least one major tier (ferrite + topology compensation) is at/near late PoC to early production-prototype race, while the higher-performance rare-earth-free candidates are mostly prototype-stage with unresolved scale/manufacturing constraints. [64]

## ART 07.053 Nano-Engineered Membranes for Low-Energy Desalination

### ART extraction

148. ART extraction

#### A) Primary capability claimed (what the ART aims to do)

- Deliver **higher water permeability at comparable salt rejection** in desalination-relevant membranes, so the same permeate quality can be achieved with **lower pressure/energy or fewer elements**.
- Extend **stable run time** by reducing fouling and scaling (less flux decline, better flux recovery) so plants need **less frequent cleaning and maintenance**.
- Maintain compatibility with **existing module/pressure-vessel hardware** (i.e., “drop-in” membrane element/cartridge form factors) while improving reliability and operability.

#### B) Key sub-components / variants

- **Nanostructured selective layers** (ultrathin polyamide variants, controlled nanovoids, “uniform pathways” via modified interfacial polymerisation or additives).
- **Thin-film nanocomposite (TFN) RO membranes** (nanofillers such as MOF nanosheets, graphene-derived additives, or other nanomaterials embedded in/near the polyamide layer).
- **Graphene-derived surface coatings/layers** (e.g., graphene oxide layers deposited/assembled with controllable density; “defect-coverage” coatings; tuned surface chemistry).
- **Anti-fouling / anti-scaling surface chemistries** (small-molecule grafting, methylation/charge control, hydrophilic or low-interaction-energy functional groups).
- **Manufacturing scale-up methods** (roll-to-roll casting/coating, large-area defect control, reproducibility, mechanical robustness under cyclic pressure).
- **Embedded monitoring / “smart” operation hooks** (sensing approaches for in-situ identification of concentration polarisation vs foulant deposition; improved control interfaces for cleaning cycles).

#### C) Maturity indicators that would count as strong evidence for this ART

- **Pilot-scale or roll-to-roll fabrication** (hundreds of m<sup>2</sup>-scale batches, reproducible performance across batches, not just lab coupons).
- **Desalination-relevant operating tests** (e.g., seawater-strength salinity and pressures; stable rejection; multi-cycle fouling/cleaning performance).
- **Demonstrated anti-fouling and/or anti-scaling metrics** (lower flux decline ratio, higher flux recovery ratio, longer cleaning intervals).
- **System-level energy/footprint analysis tied to membrane permeability** (quantified potential SEC reduction or pressure-vessel reduction with realistic constraints such as

concentration polarisation).

- **Commercial product evidence** (dated technical manuals/datasheets; large-scale orders/deployments; multiple major manufacturers involved).

## Evidence

149. Evidence (10–20 recent, reliable sources)

### 1) Pilot scale fabrication of low fouling seawater desalination thin film composite reverse osmosis membrane

**Author(s):** Parthapratim Bera[1] et al.

**Venue/type:** *Desalination* (peer-reviewed experimental paper)

**Date:** October 2024

**Link:** <https://doi.org/10.1016/j.desal.2024.117790>

**Why it matters:** Demonstrates **pilot-scale roll-to-roll** production (100 m<sup>2</sup>/batch) of a seawater TFC RO membrane where **PEG is incorporated during fabrication**, increasing pure water permeance from **1.4 to 2.2 LMH/bar** while maintaining **~98.4–98.8% NaCl rejection** and improving antifouling (flux recovery ratio **87% vs 67%**). [2]

### 2) Development and Industrial-Scale Fabrication of Next-Generation Low-Energy Membranes for Desalination

**Organisation/author(s):** Li May Goh[3] et al. (START, Nanyang Technological University—NTUitive)

**Venue/type:** *Membranes* (peer-reviewed “Communication”, strongly manufacturing-focused)

**Date:** May 2022

**Link:** <https://doi.org/10.3390/membranes12050540>

**Why it matters:** Provides an **industrial-scale fabrication method** that coats the PSf UF support directly onto a permeate carrier (removing non-woven backing), achieving **~9% leaf-thickness reduction** and reporting **defect-free RO membranes** with **94% salt rejection** and **40 LMH flux** (2000 mg/L NaCl, 15 bar)—concrete evidence toward **manufacturing/packaging innovations** that can lower energy by increasing membrane area per module volume. [4]

### 3) Thin film nanocomposite membrane incorporated with 2D-MOF nanosheets for highly efficient reverse osmosis desalination

**Author(s):** Yi Liu[5] et al.

**Venue/type:** *Journal of Membrane Science* (peer-reviewed experimental paper)

**Date:** July 2022

**Link:** <https://doi.org/10.1016/j.memsci.2022.120520>

**Why it matters:** Shows a TFN RO strategy using **ultrathin nickel-based 2D-MOF nanosheets**: water permeance increases to **50.0 L·m<sup>-2</sup>·h<sup>-1</sup>·MPa<sup>-1</sup>** (vs 20.6 baseline) while keeping **~99.2% NaCl rejection**, and reports strong antifouling behaviour (water permeance recovery ratio **96.9%** against humic acid). [6]

### 4) High-Performance Polyamide Reverse Osmosis Membrane Containing Flexible Aliphatic Ring for Water Purification

**Author(s):** Chi Jiang[7] et al.

**Venue/type:** *Polymers* (peer-reviewed experimental paper)

**Date:** February 2023

**Link:** <https://doi.org/10.3390/polym15040944>

**Why it matters:** Reports a modified interfacial-polymerisation chemistry (piperidine additive) achieving **2.96 LMH/bar** water permeance and **99.4% NaCl rejection**, plus an operational stability test showing performance remaining stable for **~45 h**—directly relevant to the “higher permeability at high rejection” claim. [8]

**5) Fouling-resistant reverse osmosis membranes grafted with 2-aminoethanethiol having a low interaction energy with charged foulants**

**Author(s):** Jun Xiao[9] et al.

**Venue/type:** *npj Clean Water* (peer-reviewed experimental paper; open access)

**Date:** April 2024

**Link:** <https://www.nature.com/articles/s41545-024-00326-5>

**Why it matters:** Uses a “design-for-low-interaction-energy” surface chemistry approach (AET grafting) that increases water permeance from **2.6 ± 0.1 to 3.2 ± 0.05 LMH/bar** (≈23%) and targets fouling by **small charged surfactants**, aligning with the ART’s anti-fouling mechanism emphasis. [10]

**6) Graphene Oxide Surface Modification of Reverse Osmosis Membrane via Langmuir–Blodgett Technique: Balancing Performance and Antifouling Properties**

**Author(s):** Dmitrii I. Petukhov[11] et al.

**Venue/type:** *Membranes* (peer-reviewed experimental paper; open access)

**Date:** August 2024

**Link:** <https://doi.org/10.3390/membranes14080172>

**Why it matters:** Demonstrates a controllable **graphene-oxide coating process** (Langmuir–Blodgett transfer) on a commercial RO membrane, reporting that at an optimal coating density the flux decline ratio drops from **38% to 18%** and flux recovery rises from **~65% to ~87%**, while NaCl rejection increases from **95.2% to 98.1%** (at the expense of some permeance). [12]

**7) Methylation of reverse osmosis membrane for superior anti-fouling performance via blocking carboxyl groups in polyamide**

**Author(s):** Yiwen Qin[13] et al.

**Venue/type:** *Nature Water* (peer-reviewed experimental paper; abstract accessible)

**Date:** January 2025

**Link:** <https://www.nature.com/articles/s44221-024-00371-x>

**Why it matters:** Reports an interfacial-polymerisation-stage methylation approach (dimethylamine grafting) achieving **3.84 LMH/bar** water permeance with **99.05% NaCl rejection**, and claims antifouling performance surpassing a named commercial antifouling RO membrane product—strong evidence that **surface chemistry control** can push both permeability and fouling resistance in desalination-style membranes. [14]

**8) Scalable aqueous-phase fabrication of reduced graphene oxide nanofiltration membranes by an integrated roll-to-roll process**

**Organisation/author(s):** Amirsalar R. Esfahani[15] et al.; indexed by U.S. Department of Energy Office of Scientific and Technical Information[16]

**Venue/type:** *Journal of Membrane Science* (peer-reviewed article; manufacturing evidence via OSTI record)

**Date:** April 2023

**Link:** <https://doi.org/10.1016/j.memsci.2023.121669>

**Why it matters:** While focused on nanofiltration, it provides rare **large-area manufacturing data** for graphene-derived membranes: reports **90 × 30 cm** roll-to-roll-fabricated rGO membranes (~100 nm thick, 2700 cm<sup>2</sup> area) and gives performance under harsh conditions, helping de-risk the ART's "defect-free manufacturing at scale" bottleneck for 2D-material-based membranes. [17]

**9) Dynamic Monitoring of Reverse Osmosis Process via Electrical Impedance Tomography: Enabling In Situ Visualization and Uncovering Distinct Roles of Concentration Polarization and Foulant Deposition in Flux Decline**

**Author(s):** Fei Gao[18] et al.

**Venue/type:** *Environmental Science & Technology* (peer-reviewed paper; access-limited but indexed with metadata and summary)

**Date:** January 2026

**Link:** <https://doi.org/10.1021/acs.est.5c15320>

**Why it matters:** Directly supports the ART's "embedded sensing/monitoring" variant by reporting an **in situ, noninvasive** approach (EIT-based imaging) to distinguish concentration polarisation vs foulant deposition contributions to flux decline—relevant to more reliable, feedback-driven operation and cleaning schedules. [19]

**10) Supercomputing and machine learning-aided optimal design of high permeability seawater reverse osmosis membrane systems**

**Author(s):** Jiu Luo[20] et al.

**Venue/type:** *Science Bulletin* (peer-reviewed modelling + optimisation paper)

**Date:** February 2023

**Link:** <https://doi.org/10.1016/j.scib.2023.01.039>

**Why it matters:** Quantifies plausibility of energy savings at the system level: reports modelling/optimisation where energy consumption could drop by **27.5% (to 1.66 kWh/m<sup>3</sup>)** with contributions attributed to high-permeability SWRO membranes (**12.2%**) and two-stage design (**14.5%**), and explicitly treats concentration polarisation constraints. [21]

**11) Quantifying the potential of high-performance RO membranes for seawater and hypersaline brine desalination: from module-scale modelling to experimental evaluation**

**Author(s):** Yu Jie Lim[22] et al.

**Venue/type:** *Desalination* (peer-reviewed modelling + experimental evaluation)

**Date:** December 2025

**Link:** <https://doi.org/10.1016/j.desal.2025.119394>

**Why it matters:** Ties membrane properties to scaling reality: modelling suggests tripling permeability (0.45→1.35 LMH/bar) can reduce HPRO energy consumption by **23%** or reduce pressure vessels by **62%**; also experimentally tests **12 state-of-the-art commercial RO membranes** at extreme conditions (e.g., **130 bar, 70 g/L NaCl**) and reports measured permeability and rejection ranges, providing a benchmark of how close current products are to high-performance targets. [23]

**12) Ultra low-pressure reverse osmosis membrane for desalination: Current challenges and future directions**

**Author(s):** P.T.P. Aryanti[24] et al.

**Venue/type:** *Desalination* (peer-reviewed review/roadmap-style paper)

**Date:** 2023 (April noted in indexing)

**Link:** <https://doi.org/10.1016/j.desal.2023.116650>

**Why it matters:** Synthesises the technical pathway to “lower-pressure RO” and frames key constraints: e.g., cites seawater pressure requirements up to **~70 bar**, defines ULPRO ambition of **<10 bar** operation with higher flux, and discusses nanomaterials/nanocomposites and packaging (e.g., hollow-fibre prospects) as routes and barriers—useful for maturity assessment and identifying what’s still missing. [25]

### 13) 2024 roadmap on membrane desalination technology at the water-energy nexus

**Organisation/author(s):** Antonio Politano[26] et al.

**Venue/type:** *JPhys Energy* roadmap (peer-reviewed roadmap, indexed in DOAJ)

**Date:** January 2024

**Link:** <https://doi.org/10.1088/2515-7655/ad2cf2>

**Why it matters:** Provides authoritative framing of maturity and bottlenecks for membrane desalination: states SWRO is **>70% of global desalination capacity**, and that energy consumption is typically **3–5 kWh/m<sup>3</sup>** versus a cited theoretical **~1.1 kWh/m<sup>3</sup>** at 50% recovery—context that supports why permeability/fouling improvements remain valuable yet bounded by system/thermodynamic limits. [27]

### 14) FilmTec Reverse Osmosis Membranes Technical Manual

**Organisation:** DuPont Water Solutions[28] (vendor technical doc)

**Venue/type:** Vendor technical manual (design/operation limits, element construction, troubleshooting)

**Date:** September 2025 (Rev. 18)

**Link:**

<https://www.dupont.com/content/dam/water/amer/us/en/water/public/documents/en/RO-NF-FilmTec-Manual-45-D01504-en.pdf>

**Why it matters:** A dated, detailed technical manual is strong “market maturity” evidence: it codifies engineering limits (pressure drop, feed pressure), element construction, and operational practices needed for large-scale deployment, indicating RO membrane elements are **industrialised consumables** integrated into standard plant design and operations. [29]

### 15) FilmTec Seawater Elements product documentation

**Organisation:** DuPont FilmTec (vendor technical doc)

**Venue/type:** Vendor product datasheet for seawater RO elements

**Date:** October 2024

**Link:**

<https://www.dupont.com/content/dam/water/amer/us/en/water/public/documents/en/RO-FilmTec-SW30-Seawater-PDS-45-D01519-en.pdf>

**Why it matters:** Dated product documentation for seawater elements supports “close-to-market / in-market” maturity—these documents typically specify standardised test conditions and minimum performance (flow, salt rejection), consistent with commercial procurement and deployment in SWRO plants. [30]

### 16) TORAY Report 2024

**Organisation:** Toray Industries[31] (annual/integrated reporting; industry deployment evidence)

**Venue/type:** Corporate report with deployment/order information

**Date:** November 2024

**Link:** [https://www.toray.com/ir/pdf/lib/lib\\_a541.pdf](https://www.toray.com/ir/pdf/lib/lib_a541.pdf)

**Why it matters:** Reports that Toray received an **order for reverse osmosis membranes** for

the **Yanbu 4** seawater desalination plant in Saudi Arabia, providing concrete evidence that advanced RO membranes are procured and deployed in **large infrastructure projects**, consistent with late-stage maturity in core RO element technology. [32]

#### **Maturity score and reasoning**

150. Maturity score (1–7) and reasoning

#### **A) Final maturity score: 6**

##### **Evidence-to-rubric mapping**

##### **Why the evidence rules out levels 1–5**

- The ART is not only a lab-verified concept: multiple sources show **pilot/industrial-scale manufacturing** of modified membranes compatible with standard spiral-wound architectures. The Bera et al. study reports **pilot-scale roll-to-roll SWRO membrane fabrication** (100 m<sup>2</sup>/batch) with quantified gains in permeance and antifouling while maintaining seawater-relevant rejection. [2]
- Manufacturing/process integration is explicitly demonstrated: Goh et al. describe **industrial-scale fabrication steps** (slot-die casting parameters, scaling from small batches up to large batches) and show a packaging-driven pathway to “low energy” via increased membrane area per housing. [4]
- There is clear evidence of **commercial productisation** in the broader class of high-performance RO membranes: a current vendor technical manual (Rev. Sept 2025) and seawater element product documentation (Oct 2024) indicate mature, standardised products delivered to design engineers and operators as deployable components. [33]
- Market-scale adoption of RO membranes in major infrastructure is evidenced by a large manufacturer reporting orders for SWRO plants (Toray’s Yanbu 4 order). [32]

Together, this combination (pilot-scale manufacturing + dated vendor manuals/datasheets + infrastructure orders) is most consistent with **Level 6: products delivered to customers; scaling and application expansion ongoing**.

##### **What is still missing to justify level 7 for this ART as written**

- The ART description’s more radical variants—especially **graphene-derived selective films as primary RO desalination layers** and **sensor-integrated “smart membrane cartridges”**—lack clear evidence of **broad, multi-customer commercial delivery at increasing volumes** and multi-year field reliability in desalination duty. The sensing thread is promising but still best evidenced as research/monitoring demonstration rather than a widely deployed standard module feature. [19]
- A level-7 case would be strengthened by public evidence of **multiple competing product lines** explicitly based on these nano-engineered variants (e.g., graphene-enabled coatings/elements) being shipped at scale, along with clear indicators of rising demand for those specific variants (not just RO generally). The roadmap also highlights that SWRO energy and recovery are still constrained by system and thermodynamic factors, implying that even better membranes must prove value under realistic concentration polarisation/fouling constraints. [34]

#### **C) Sub-component view and aggregation to one score**

Because the ART bundles materially different technology threads under the same “better RO

membranes” functionality, a sub-score view is appropriate; the final score is an average-weighted judgement emphasising the *core deliverable* (*membrane elements that drop into existing hardware*).

- **Scaled polyamide/TFC nano-engineering (additives, ultrathin-layer control, TFN fillers) → ~5–6**  
Evidence: pilot/roll-to-roll SWRO membrane modification with quantified improvements [2]; industrial-scale packaging/fabrication method for “low-energy” elements [4]; multiple lab demonstrations reaching high permeance at high rejection [35].
- **Graphene-derived surface coatings for fouling control / defect coverage → ~3–4**  
Evidence: controlled GO coating improves fouling metrics and can raise rejection, but with trade-offs and limited demonstration scope [12]; manufacturing scale-up for graphene-derived membranes is demonstrated in related contexts, but not yet clearly as mainstream RO desalination elements [17].
- **Embedded sensing / feedback-control enabling membranes → ~3**  
Evidence: EIT-based in situ monitoring appears as a research-level capability that supports the plausibility of “smart” operation but is not yet shown as a standardised shipped RO element feature. [19]
- **Commercial delivery of high-performance RO elements compatible with existing hardware → 6–7 for the baseline product class**  
Evidence: current technical manuals/datasheets and major plant orders indicate mature deployment of RO membrane products (even if not always explicitly “graphene-enabled”). [36]

**Aggregation rationale:** the ART’s *core value proposition*—better membranes in existing modules reducing energy/maintenance—is already in **commercial delivery and scaling** (supporting ≥6), while the “most radical” materials and smart-sensing variants lag (pulling the technology bundle below a confident 7). The resulting single-score best fit is **6**.

## ART 07.054 Ultra-Wide-Bandgap (UWBG) Power Semiconductors

### ART extraction

#### A) Primary capability claimed (what the ART does)

- Enable **power switches and diodes** that can block **higher voltages in thinner layers** and switch with **lower resistive loss** than silicon (and often beyond today's SiC/GaN limits),

enabling smaller, higher-efficiency converters.

- Operate at **higher junction temperatures** and potentially **higher switching frequencies**, reducing cooling and passive-component burden.
- Provide a route to **standardised power modules** (packaged devices) that integrate sensing/diagnostics while remaining “plug compatible” with conventional control interfaces (future-state claim; evidence target is modules + reliability + manufacturability).

## B) Key sub-components / variants (sub-threads to track)

- **$\beta$ -Ga<sub>2</sub>O<sub>3</sub> (gallium oxide) power diodes**: Schottky barrier diodes (SBD), heterojunction / p–n–style diodes using external p-type oxides (e.g., NiO, Cr<sub>2</sub>O<sub>3</sub>-based) to compensate for lack of native p-type Ga<sub>2</sub>O<sub>3</sub>. [1]
- **$\beta$ -Ga<sub>2</sub>O<sub>3</sub> power transistors** (lateral MOSFET/JFET-like structures; long-term aspiration toward robust vertical device architectures). [2]
- **Wafer and epitaxy scaling for  $\beta$ -Ga<sub>2</sub>O<sub>3</sub>** (melt growth, EFG/CZ-like methods, epilayer uniformity, defect density control, larger diameters). [3]
- **Thermal management / packaging for  $\beta$ -Ga<sub>2</sub>O<sub>3</sub>** (intrinsically low thermal conductivity → need advanced heat spreaders, double-sided cooling, heterogeneous integration). [4]
- **Diamond power devices** (Schottky/Schottky-pn concepts, high-temperature operation; materials/dopant activation constraints). [5]
- **Diamond MOSFETs (n-channel and p-channel)** as a prerequisite for diamond CMOS and, longer-term, broader diamond power-electronics ecosystems. [6]
- **$\beta$ -Ga<sub>2</sub>O<sub>3</sub>-on-diamond** (or on polycrystalline diamond) as an engineered heat-spreader platform to mitigate self-heating and enable higher current density / reliability. [7]

## C) Maturity indicators that would count as evidence

- **Device-level milestones**: multi-kV blocking with **credible on-resistance / PFOM**, temperature operation ( $\geq 150$ – $200$  °C for power;  $> 300$  °C for harsh environments), repeatable switching, and gate/oxide stability. [8]
- **System / circuit PoC**: devices used in **real power-converter prototypes** (e.g., DC–DC stage) with measured efficiency and waveforms. [9]
- **Reliability evidence**: thermal soak, thermal cycling / power cycling, interface stability (e.g., p–n heterojunction stability), failure mechanisms identified. [10]
- **Manufacturing readiness**: wafer diameter scaling, **defect-density reduction**, epi uniformity control, and documented yields for large-area devices. [11]
- **Commercialisation signals**: multiple well-capitalised industrial actors investing in substrates/devices, pilot lines, and early customer sampling (with measurable device specs). [12]
- **Module-level progress** (for the ART’s end-state): packaged power modules with thermal design, qualification testing, and early deployments—this is a key “missing rung” that would move maturity toward 4–6. [13]

## 2. Evidence (10–20 recent, reliable sources)

### 1) Ultra-wide bandgap semiconductor Ga<sub>2</sub>O<sub>3</sub> power diodes [14]

- **Authors/organisation**: Jincheng Zhang et al.
- **Venue/type**: *Nature Communications* (peer-reviewed experimental paper; open access)
- **Publication date**: July 2022
- **Link**: <https://www.nature.com/articles/s41467-022-31664-y>
- **What it reports / why it matters**: Demonstrates Ga<sub>2</sub>O<sub>3</sub> heterojunction PN diodes using hole

injection to achieve **8.32 kV breakdown**, **5.24 mΩ·cm<sup>2</sup> specific on-resistance**, and **13.2 GW/cm<sup>2</sup> PFOM**, directly supporting plausibility that Ga<sub>2</sub>O<sub>3</sub> can reach multi-kV class performance with competitive conduction loss. [14]

## 2) Vacuum Annealed β-Ga<sub>2</sub>O<sub>3</sub> Recess Channel MOSFETs With 8.56 kV Breakdown Voltage [2]

- **Authors/organisation:** Shivam Sharma et al.
- **Venue/type:** *IEEE Electron Device Letters* (peer-reviewed experimental paper; author PDF via NSF public access)
- **Publication date:** December 2022
- **Link:** <https://par.nsf.gov/servlets/purl/10444744>
- **What it reports / why it matters:** Reports a lateral field-plated β-Ga<sub>2</sub>O<sub>3</sub> MOSFET with **8.56 kV breakdown** (for Lgd = 60 μm) plus process insight that **vacuum annealing can improve/on-resistance recovery after etch damage** without reducing breakdown—evidence that key integration/process bottlenecks (etch damage recovery) are being actively engineered toward usable devices. [15]

## 3) 10-kV Ga<sub>2</sub>O<sub>3</sub> Charge-Balance Schottky Rectifier Operational at 200 °C [16]

- **Authors/organisation:** Yuan Qin et al. (incl. Virginia Tech and collaborators listed in the paper)
- **Venue/type:** *IEEE Electron Device Letters* (peer-reviewed experimental paper; author PDF via NSF public access)
- **Publication date:** August 2023
- **Link:** <https://par.nsf.gov/servlets/purl/10464205>
- **What it reports / why it matters:** Demonstrates a lateral Ga<sub>2</sub>O<sub>3</sub> SBD with **>10 kV breakdown** using a **NiO RESURF charge-balance** concept and shows **thermal stability up to 200 °C**, addressing two maturity-critical claims for power use: **multi-kV blocking** and **elevated-temperature operation**. [16]

## 4) Large-area β-Ga<sub>2</sub>O<sub>3</sub> Schottky barrier diode and its application in DC–DC converters [9]

- **Authors/organisation:** Wei Guo et al. (University of Science and Technology of China)
- **Venue/type:** *Journal of Semiconductors* (peer-reviewed experimental paper; PDF)
- **Publication date:** 2023 (issue 44(7))
- **Link:** <https://www.researching.cn/ArticlePdf/m00098/2023/44/7/072805.pdf>
- **What it reports / why it matters:** Shows a **large-area vertical β-Ga<sub>2</sub>O<sub>3</sub> SBD (1×1 mm<sup>2</sup>)** delivering **8 A forward current** and **612 V reverse breakdown**, then demonstrates a **β-Ga<sub>2</sub>O<sub>3</sub> SBD-based DC–DC converter with 95.81% efficiency**, providing system-level PoC evidence beyond single-device characterisation. [9]

## 5) Growth of bulk β-Ga<sub>2</sub>O<sub>3</sub> crystals from melt without precious-metal crucible by pulling from a cold container [17]

- **Authors/organisation:** A. Yoshikawa et al.
- **Venue/type:** *Scientific Reports* (peer-reviewed experimental paper; open access)
- **Publication date:** June 2024
- **Link:** <https://www.nature.com/articles/s41598-024-65420-7>
- **What it reports / why it matters:** Demonstrates a melt-growth route (OCCC) eliminating precious-metal crucibles and reports **β-Ga<sub>2</sub>O<sub>3</sub> crystals up to 46 mm diameter**, directly addressing the ART's manufacturability bottleneck (substrate cost/scale-up) and showing progress toward scalable wafer supply. [17]

## 6) 2 in. Bulk $\beta$ -Ga<sub>2</sub>O<sub>3</sub> Single Crystals Grown by EFG Method with High Wafer-Scale Quality [18]

- **Authors/organisation:** Ganrong Feng et al.
- **Venue/type:** *ACS Omega* (peer-reviewed experimental paper; free via PubMed Central)
- **Publication date:** April 2024
- **Link:** <https://pmc.ncbi.nlm.nih.gov/articles/PMC11112554/>
- **What it reports / why it matters:** Reports **2-inch  $\beta$ -Ga<sub>2</sub>O<sub>3</sub> bulk crystals** and wafer-quality metrics (e.g., **mean X-ray rocking curve FWHM ~60.8 arcsec** and **RMS roughness ~0.196 nm**), supporting the plausibility of wafer-scale substrates with epi-ready surface quality—an essential precursor to any “standardised module” supply chain. [18]

## 7) Third-generation gallium-oxide 100-mm epitaxial wafer with ten times fewer killer defects [19]

- **Authors/organisation:** Novel Crystal Technology, Inc.; Saga University; NEDO (New Energy and Industrial Technology Development Organization, Japan)
- **Venue/type:** **Industry/government programme press release** with quantitative manufacturing + prototype metrics (treat as vendor/government evidence; not peer review)
- **Publication date:** March 2022
- **Link:** <https://www.novelcrystal.co.jp/eng/2022/1162/>
- **What it reports / why it matters:** Reports a **100-mm Ga<sub>2</sub>O<sub>3</sub> epitaxial wafer** with **killer defect density reduced to ~0.7 cm<sup>-2</sup>** (claimed <1/10 of prior generation), plus quantified **film thickness (~10  $\mu$ m  $\pm$ 5%)** and **donor concentration (~1 $\times$ 10<sup>16</sup> cm<sup>-3</sup>  $\pm$ 7%)** uniformity and large-chip prototyping (up to **10 mm $\times$ 10 mm**)—strong maturity evidence for manufacturability, though still requiring independent validation for market readiness. [19]

## 8) Mitsubishi Electric Buys Stake in Novel Crystal Technology to Accelerate Development of Gallium-oxide Power Semiconductors [20]

- **Authors/organisation:** Mitsubishi Electric Corporation
- **Venue/type:** Industry corporate disclosure / press release (commercialisation signal; not a technical validation)
- **Publication date:** July 2023
- **Link:** <https://meus-semiconductors.com/news-events/mitsubishi-electric-buys-stake-in-novel-crystal-technology-to-accelerate-development-of-gallium-oxide-power-semiconductors>
- **What it reports / why it matters:** States Mitsubishi Electric has taken an **equity position** in a Ga<sub>2</sub>O<sub>3</sub> wafer supplier (NCT) to **accelerate development** of gallium-oxide power semiconductors—evidence of well-capitalised industrial involvement consistent with movement beyond “only academic curiosity,” even if product shipments at scale are not yet demonstrated. [20]

## 9) Reliable operation of Cr<sub>2</sub>O<sub>3</sub>:Mg/ $\beta$ -Ga<sub>2</sub>O<sub>3</sub> p–n heterojunction diodes during extended operation at 600 °C [10]

- **Authors/organisation:** W.A. Callahan et al. (document hosted via NREL/OSTI; APL paper)
- **Venue/type:** *Applied Physics Letters* (peer-reviewed experimental paper; open PDF)
- **Publication date:** April 2024
- **Link:** <https://docs.nrel.gov/docs/fy24osti/87958.pdf>
- **What it reports / why it matters:** Demonstrates extended high-temperature operation: diodes cycled **25 $\leftrightarrow$ 550 °C (30 cycles)** and soaked **140 h at 600 °C**, with quantified drift in

turn-on voltage and on-state resistance and interface chemical changes (Mg/MgO accumulation), giving rare, concrete **reliability evidence** for “high-T operation” claims while also exposing remaining stability gaps. [10]

#### 10) Van der Waals $\beta$ -Ga<sub>2</sub>O<sub>3</sub> thin films on polycrystalline diamond substrates [21]

- **Authors/organisation:** Jing Ning et al.
- **Venue/type:** *Nature Communications* (peer-reviewed experimental paper; open access)
- **Publication date:** August 2025
- **Link:** <https://www.nature.com/articles/s41467-025-63666-x>
- **What it reports / why it matters:** Reports  $\beta$ -Ga<sub>2</sub>O<sub>3</sub> thin films grown on **high-thermal-conductivity polycrystalline diamond** via van der Waals coupling to address self-heating, explicitly targeting the key limitation that **wafer-scale single-crystal diamond** and lattice mismatch otherwise impose—evidence that the “Ga<sub>2</sub>O<sub>3</sub> + engineered diamond thermal platform” pathway is experimentally advancing. [21]

#### 11) Insight into Interfacial Heat Transfer of $\beta$ -Ga<sub>2</sub>O<sub>3</sub>/Diamond Heterostructures via the Machine Learning Potential [22]

- **Authors/organisation:** Zhanpeng Sun et al.
- **Venue/type:** *ACS Applied Materials & Interfaces* (peer-reviewed; author-archived PDF; computational + interface-physics focus)
- **Publication date:** June 2024
- **Link:** [https://cronfa.swan.ac.uk/Record/cronfa68005/Download/68005\\_\\_32619\\_\\_2b412c28aaad429f86a3db0d9c9f35cf.pdf](https://cronfa.swan.ac.uk/Record/cronfa68005/Download/68005__32619__2b412c28aaad429f86a3db0d9c9f35cf.pdf)
- **What it reports / why it matters:** Focuses on **thermal boundary resistance (TBR)** in  $\beta$ -Ga<sub>2</sub>O<sub>3</sub>/diamond stacks and cites experimental TBC levels (e.g., a reported  $\sim 179 \text{ MW}\cdot\text{m}^{-2}\cdot\text{K}^{-1}$  for interfacial bonding as a comparison point), clarifying that **interfaces—not just bulk diamond conductivity—can dominate real heat flow**, a core constraint for any “high-junction-temperature module” roadmap. [23]

#### 12) Wide Bandgap Power Electronics Strategic Framework [24]

- **Authors/organisation:** U.S. Department of Energy (DOE), Office of Energy Efficiency & Renewable Energy (AMMTO)
- **Venue/type:** Government strategic framework / roadmap report
- **Publication date:** January 2025
- **Link:** [https://www.energy.gov/sites/default/files/2025-01/AMMTO%20Draft%20WBG%20PE%20Strategic%20Framework\\_FINAL.pdf](https://www.energy.gov/sites/default/files/2025-01/AMMTO%20Draft%20WBG%20PE%20Strategic%20Framework_FINAL.pdf)
- **What it reports / why it matters:** Explicitly flags **gallium oxide** as offering **extremely high breakdown voltages** with potential for ultra-high-voltage applications, and frames packaging/passives as crucial to realising benefits—useful context for maturity scoring because it highlights that **system-level packaging** remains a central bottleneck even for advanced materials. [25]

#### 13) World’s First N-Channel Diamond Field-Effect Transistor [6]

- **Authors/organisation:** National Institute for Materials Science (NIMS), Japan
- **Venue/type:** National lab press release summarising a peer-reviewed result (links to *Advanced Science*)
- **Publication date:** January 2024
- **Link:** <https://www.nims.go.jp/eng/press/2024/01/202401250.html>

- **What it reports / why it matters:** Reports the first fabricated **n-channel diamond MOSFET** and cites **field-effect mobility  $\sim 150 \text{ cm}^2/\text{V}\cdot\text{s}$  at  $300^\circ\text{C}$** , a key plausibility milestone for diamond electronics (especially CMOS enablement), but still far from “power module” maturity (voltage/current rating, wafer supply, packaging). [6]

#### 14) Diamond p-Type Lateral Schottky Barrier Diodes with High Breakdown Voltage (4612 V at 0.01 mA/mm) [26]

- **Authors/organisation:** Zhuoran Han; Can Bayram

- **Venue/type:** *IEEE Electron Device Letters* (peer-reviewed experimental paper; bibliographic record with embedded abstract)

- **Publication date:** October 2023

- **Link:** <https://experts.illinois.edu/en/publications/diamond-p-type-lateral-schottky-barrier-diodes-with-high-breakdow/>

- **What it reports / why it matters:** Demonstrates diamond lateral SBDs with  $\text{Al}_2\text{O}_3$  field plates that remain **stable under 4612 V reverse bias** (vs 1159 V without field plate), plus rectifying ratios  $>10^7$ —evidence that diamond diodes can reach kV-class blocking, directly supporting plausibility while still not evidencing scaling/manufacturing maturity. [26]

#### 15) Vertical Schottky diode on (113) oriented homoepitaxial diamond [27]

- **Authors/organisation:** P. Hazdra et al.

- **Venue/type:** *Diamond and Related Materials* (peer-reviewed experimental paper; ScienceDirect preview includes metrics)

- **Publication date:** June 2024

- **Link:**

<https://www.sciencedirect.com/science/article/abs/pii/S0925963524003935>

- **What it reports / why it matters:** Reports vertical diamond Schottky diode performance including  **$J_F \approx 100 \text{ A/cm}^2$  at 4 V** with  **$R_{\text{on,sp}} \approx 3.7 \text{ m}\Omega\cdot\text{cm}^2$**  and extremely low leakage ( $\approx 10^{-9} \text{ A/cm}^2$  regime), with discussion of **dopant activation depth/compensation** and breakdown field ( $\sim 3 \text{ MV/cm}$ ), illustrating concrete progress while also underscoring diamond’s dopant/termination challenges. [27]

#### 16) Dopants and defects in ultra-wide bandgap semiconductors [28]

- **Authors/organisation:** John L. Lyons; Darshana Wickramaratne; Anderson Janotti

- **Venue/type:** *Current Opinion in Solid State and Materials Science* (peer-reviewed review; ScienceDirect preview includes key claims)

- **Publication date:** June 2024

- **Link:**

<https://www.sciencedirect.com/science/article/abs/pii/S1359028624000147>

- **What it reports / why it matters:** Synthesises that the “most serious materials challenge” is **conductivity control** and that many leading UWBG candidates (explicitly including  **$\text{Ga}_2\text{O}_3$  and diamond**) struggle to achieve **bipolar conductivity**, which directly impacts device architectures (e.g., junction termination, normally-off devices) and therefore slows maturity toward mass-manufacturable power modules. [28]

### 3. Maturity score (1–7) and reasoning

#### A) Final maturity score: 3

#### B) Evidence-to-rubric mapping (why 3, why not lower, what is missing for 4+)

### What rules out levels 1–2 (purely theoretical / early lab verification)?

- Multiple independent peer-reviewed demonstrations show **multi-kV device prototypes** in  $\text{Ga}_2\text{O}_3$ , including **8.32 kV heterojunction PN diodes** with quantified low on-resistance and high PFOM [14], a **10-kV-class  $\text{Ga}_2\text{O}_3$  charge-balance Schottky rectifier** that remains operational up to **200 °C** [16], and **8.56 kV  $\beta\text{-Ga}_2\text{O}_3$  MOSFETs** with process steps explicitly aimed at manufacturable device recovery after etch damage. [2]
  - Diamond also has peer-reviewed kV-class diode evidence (e.g., stability to **4612 V** in lateral diamond SBDs with field plates) and vertical diode metrics demonstrating low on-resistance and very low leakage regimes. [29]
- These are beyond “operating principle in the lab” and constitute real device prototypes.

### What supports level 3 specifically (laboratory prototype demonstrated)?

- The evidence base is dominated by **laboratory prototypes** with headline performance numbers (kV blocking; temperature operation), plus early system demonstrations such as a  **$\text{Ga}_2\text{O}_3$ -diode DC–DC converter prototype** with measured **95.81% efficiency**. [9]
- Wafer and defect work shows meaningful manufacturing-relevant progress (e.g., **2-inch bulk EFG wafers with quantified rocking-curve/roughness metrics** and **100-mm epi wafer defect-density reduction claims**), but this is still best interpreted as “enabling infrastructure improving,” not yet a validated high-yield mass production supply chain. [11]
- Reliability/qualification evidence exists but is still at the “expose failure modes” stage: e.g., high-temperature cycling/soak experiments reveal interface-driven degradation mechanisms in  $\text{Ga}_2\text{O}_3$  heterojunction diodes, signalling active progress but not yet industrial qualification. [10]

### What is still missing for level 4 (PoC meeting commercialisation requirements) and level 5 (multiple actors racing to production prototypes)?

- The ART’s end-state is **standardised power modules** with robust packaging, diagnostics, and high-temperature/high-voltage qualification. Current evidence is mostly **device-level and early circuit PoC**, not sustained proof that packaged modules meet commercial reliability requirements such as long power-cycling life, repeatable thermal impedance, high-voltage partial discharge robustness, and manufacturable packaging stacks at scale. [13]
- Thermal management remains a recognised blocking issue ( $\text{Ga}_2\text{O}_3$ ’s low thermal conductivity; interface-limited heat flow even when diamond is introduced), and the “ $\text{Ga}_2\text{O}_3$ -on-diamond” approach is still in the experimental/heterostructure stage rather than a proven manufacturable module platform. [7]
- There are strong commercialisation signals (e.g., a major industrial actor taking an equity stake in a  $\text{Ga}_2\text{O}_3$  wafer supplier), but this alone does not demonstrate “production prototype finishing phase” or “products delivered in increasing amounts.” [20]

### C) Sub-component maturity breakdown and aggregation to one score

- **$\beta\text{-Ga}_2\text{O}_3$  power diodes (SBD, heterojunction/PN concepts): maturity ~4 (upper-3 to 4)** based on kV-class devices with strong PFOM and temperature operation [30] plus at least one converter-level PoC. [9]
- **$\beta\text{-Ga}_2\text{O}_3$  transistors (MOSFET-class): maturity ~3** because devices exist at multi-kV breakdown (evidence of prototype success) but broader commercial requirements

(packaging, ruggedness, lifetime, gate stack qualification) are not yet evidenced at module level. [31]

- **Wafer/epi scale-up for Ga<sub>2</sub>O<sub>3</sub>: maturity ~3–4** because multi-inch and 100-mm class efforts show quantified defect/uniformity progress, including 2-inch bulk wafer quality metrics and 100-mm epi uniformity/defect claims. [11]
- **Diamond power diodes: maturity ~3** (kV-class lateral blocking has been shown; vertical diode structures show strong conduction/leakage metrics), but scaling and doping/termination constraints remain central, keeping it in prototype territory rather than production readiness. [32]
- **Diamond MOSFETs (especially n-channel): maturity ~2–3** because a first n-channel MOSFET demonstration exists with high-temperature mobility, but evidence of power-device voltage/current classes and manufacturability is still sparse. [6]
- **Ga<sub>2</sub>O<sub>3</sub>-on-diamond thermal platforms: maturity ~2–3** because experimental heterostructure demonstrations exist, but interface/thermal boundary constraints and wafer-scale integration remain active research topics. [7]

**Aggregation:** Because the ART explicitly bundles **two distinct UWBG material families (Ga<sub>2</sub>O<sub>3</sub> and diamond)** that are at different maturity levels, and because the “standardised module” outcome depends on the slowest elements (thermal packaging + wafer quality + reliability), an **average-weighted assessment yields ~3 overall**, rather than assigning the maximum sub-score. [33]

## ART 07.055 Solid Hydrogen Storage Materials for Safe, Dense Fuel

### ART extraction

#### Primary capability claimed

- Convert hydrogen storage from a high-pressure/cryogenic containment problem into a **materials-based** storage problem by storing hydrogen in **solids** (reversible “sponge” behaviour: charge by pressure/temperature; discharge by heat/pressure swing).
- Achieve **higher volumetric density at lower pressures** than compressed gas storage, enabling safer, container-like or cartridge form factors, with passive safety features.

- Enable **modular, instrumented storage modules** (heat exchangers + sensors + control) that can be integrated into familiar geometries and refuelling/handling workflows.

#### Key sub-components and variants

- **Reversible metal hydrides** (e.g., TiFe- and TiMn-based alloys; AB/AB<sub>2</sub>/HEA families) with engineered heat management and impurity tolerance.
- **Metal hydride systems** (tanks/modules) with thermal coupling (e.g., PCM heat buffers), embedded heat exchangers, safety interlocks, and controlled discharge.
- **Metal hydride compressors / infrastructure components** that use hydrides for compression/conditioning, linking storage to refuelling.
- **Cryo-adsorption in porous solids** (MOFs / ZIFs / engineered carbons): hydrogen stored by physisorption onto high-surface-area internal pores at cryogenic temperatures.
- **Shaping & densification** of porous adsorbents (monoliths/pellets/extrudates) to improve packing density and volumetric performance (without crippling porosity).
- **Standardisation / measurement reproducibility** (inter-laboratory benchmarks, reference materials, and protocols for adsorption storage).

#### Maturity indicators that would constitute evidence

- Demonstrated **system-level prototypes** (kg-scale hydrogen stored/released with controlled rates; integration with electrolyser/fuel cell; long-duration operation).
- Evidence of **scale-up or industrial production** of storage materials (kg-scale alloy batches; repeatable shaping lines such as extrusion/pelletisation).
- **Safety validation** beyond paper design (risk studies + experimentally supported hazard claims; self-limiting release behaviour; no spontaneous ignition on exposure).
- **Field or pre-field demonstrations** (containerised modules, on-vehicle trials, microgrid pilots; validated charge/discharge efficiency and rates).
- Signs of **commercial readiness**: product families with specifications, government procurement/NEPA documentation, funded demonstrations, integration into “real” infrastructure.

#### Evidence (10–20 recent, reliable sources)

##### Peer-reviewed materials and engineering evidence

##### **Monolithic MOF densification reaching high volumetric H<sub>2</sub> at lower pressures - Title:**

Densified HKUST-1 Monoliths as a Route to High Volumetric and Gravimetric Hydrogen Storage Capacity

- **Authors/organisation:** D. G. Madden et al. (research groups including University-based MOF teams)

- **Venue/type:** Peer-reviewed experimental paper (Journal of the American Chemical Society)

- **Date:** July 2022

- **Link:** <https://docs.nrel.gov/docs/fy22osti/83773.pdf>

- **Why it matters:** Reports a densified monolithic MOF storing **46 g H<sub>2</sub>/L (50 bar, 77 K)** and delivering **41–42 g H<sub>2</sub>/L** under a combined temperature–pressure swing (25–50 bar/77 K → 5 bar/160 K), indicating practical densification can cut operating pressure versus compressed gas and benchmark materials. [1]

**Room-temperature reversible hydrides with long cycling stability** - **Title:** High-entropy hydrides for fast and reversible hydrogen storage at room temperature: binding-energy engineering via first-principles calculations and experiments

- **Authors/organisation:** A. Mohammadi et al.
- **Venue/type:** Peer-reviewed experimental + modelling paper (Acta Materialia)
- **Date:** September 2022
- **Link:** <https://www.sciencedirect.com/science/article/abs/pii/S1359645422004980>
- **Why it matters:** Demonstrates multi-principal element alloys forming reversible hydrides at **room temperature**, with **fast kinetics**, **no activation/catalyst treatment**, and **stability for at least 1000 cycles**, addressing key durability/kinetics bottlenecks for low-temperature metal-hydride storage. [2]

**Industrial-level production of a TiFe alloy for a ~50 kg H<sub>2</sub> storage plant** - **Title:**

TiFe<sub>0.85</sub>Mn<sub>0.05</sub> alloy produced at industrial level for a hydrogen storage plant

- **Authors/organisation:** J. Barale et al.
- **Venue/type:** Peer-reviewed experimental paper (International Journal of Hydrogen Energy)
- **Date:** August 2022
- **Link:** <https://www.sciencedirect.com/science/article/pii/S0360319922029536>
- **Why it matters:** Uses **industrial-scale alloy synthesis (5 kg batch)** in the context of a **~50 kg H<sub>2</sub>** storage plant target, directly speaking to manufacturability and scale-up of the active metal-hydride material rather than only lab grams. [3]

**Validated metal-hydride tank design achieving high volumetric H<sub>2</sub> density** - **Title:**

Numerical simulation and experimental validation of Ti<sub>0.95</sub>Zr<sub>0.05</sub>Mn<sub>0.9</sub>Cr<sub>0.9</sub>V<sub>0.2</sub> alloy in a metal hydride tank for high-density hydrogen storage

- **Authors/organisation:** L. Zhan et al.
- **Venue/type:** Peer-reviewed (model + experimental validation) paper (International Journal of Hydrogen Energy)
- **Date:** November 2022
- **Link:** <https://www.sciencedirect.com/science/article/abs/pii/S0360319922041209>
- **Why it matters:** Reports a self-designed MH tank model validated against experiment and cites a **tank volumetric storage density** figure (55.1 g H<sub>2</sub>/L for the tank design context), evidencing engineering maturity around thermal/kinetic modelling and prototype tank design—not just material powder capacity. [4]

**Metal-hydride compressor integrated into small refuelling station** - **Title:** A metal hydride compressor for a small scale H<sub>2</sub> refuelling station

- **Authors/organisation:** Researchers linked to turbine/university + industrial partners (incl. industrial gas context)
- **Venue/type:** Peer-reviewed prototype/system paper (International Journal of Hydrogen Energy)
- **Date:** October 2023
- **Link:** <https://www.sciencedirect.com/science/article/pii/S0360319923024527>
- **Why it matters:** Demonstrates a **two-stage metal-hydride compressor** using commercial alloys, compressing hydrogen from **28 bar to 250 bar** (RT to 150 °C) with an average **104 NL/min** flow, integrating hydrides into refuelling infrastructure components that are tightly coupled to storage logistics. [5]

**Improving adsorbent thermal management and shaping robustness** - **Title:** Improved thermal management in HKUST-1 composites upon graphite flakes incorporation: hydrogen adsorption properties

- **Authors/organisation:** J. Farrando-Pérez et al.
- **Venue/type:** Peer-reviewed experimental paper (International Journal of Hydrogen Energy)
- **Date:** December 2023
- **Link:** <https://www.sciencedirect.com/science/article/pii/S0360319923028033>
- **Why it matters:** Shows that adding graphite flakes can reduce shaping damage (reported <10% BET loss vs 40% for pure HKUST-1 at a conforming step) while maintaining cryogenic adsorption, including a reported ~18.7 g/L volumetric excess uptake for a monolith at 0.1 MPa and -195 °C—directly targeting the “materials + heat transfer + shaping” bundle needed for practical adsorption tanks. [6]

**Mechanical densification to raise MOF deliverable capacity under TPS operation** - **Title:** Improving hydrogen storage performance of UiO-67 and MOF-177 under temperature-pressure swing conditions via densification

- **Authors/organisation:** R. Murugavel et al.
- **Venue/type:** Peer-reviewed experimental + modelling paper (International Journal of Hydrogen Energy)
- **Date:** May 2025
- **Link:** <https://www.sciencedirect.com/science/article/abs/pii/S0360319925003623>
- **Why it matters:** Reports binder-free monolithic engineering increasing bulk density by ~70% and improving deliverable capacity by 14–42% vs powders, with deliverable capacities around 47 and 44 g/L for densified MOF-177 and UiO-67 under 77 K/100 bar → 160 K/5 bar TPS—evidence that “cartridge-style” adsorbent shaping is advancing beyond powder performance claims. [7]

#### Measurement reproducibility and scale-oriented adsorbent shaping

**Pelletised ZIF-8 produced via continuous/mechanicochemical methods; usable hydrogen metric reported** - **Title:** ZIF-8 Pellets as a Robust Material for Hydrogen Cryo-Adsorption Tanks

- **Authors/organisation:** R. Balderas-Xicohtencatl et al.
- **Venue/type:** Peer-reviewed experimental paper (ACS Applied Energy Materials)
- **Date:** February 2023 (online)
- **Link:** <https://pubmed.ncbi.nlm.nih.gov/37771502/>
- **Why it matters:** Reports ZIF-8 made through twin-screw extrusion (industrialisation-relevant) and pelletisation without porosity loss, with a stated ~31 g usable H<sub>2</sub>/L of pellet under a TPS assumption (77 K/100 bar → 117 K/5 bar), and notes cycling without degradation—key maturity evidence for robust “packed bed” cryo-adsorbent cartridges. [8]

**Inter-laboratory study proposing ZIF-8 pellets as a reference material** - **Title:** Establishing ZIF-8 as a reference material for hydrogen cryoadsorption: an interlaboratory study

- **Authors/organisation:** J. A. Villajos et al.
- **Venue/type:** Peer-reviewed inter-lab benchmark paper (ChemPhysChem)
- **Date:** January 2024 (Epub) / March 2024 (issue)
- **Link:** <https://pubmed.ncbi.nlm.nih.gov/38165137/>
- **Why it matters:** Reports hydrogen uptake measured at 77 K up to 100 bar across 9 laboratories / 15 experimental setups, with stated ~3–4% relative standard deviation

between 10–100 bar, directly reducing a major maturity blocker: inconsistent adsorption measurement and the lack of reference materials for certification-grade datasets. [9]

### System prototypes, application demonstrations, and deployment signals

#### Low-pressure containerised metal-hydride storage integrated with electrolyser + fuel cell

**Title:** Risk Management in a Containerized Metal Hydride Storage System

- **Authors/organisation:** A. Rosino Messa et al.

- **Venue/type:** Peer-reviewed safety engineering + prototype description (Hydrogen Safety journal)

- **Date:** 2024

- **Link:** <https://hysafejournal.org/articles/10/files/66f3dc7304f2d.pdf>

- **Why it matters:** Describes a HyCARE container prototype storing **up to 40 kg H<sub>2</sub> in 12 TiFe-based MH tanks** at **<50 barg** and **<100 °C**, with experimentally supported safety claims (e.g., MH exposure to air/water did not cause spontaneous ignition; release rate is self-limited), directly evidencing “safe, dense, low-pressure module” plausibility. [10]

#### Vehicle-adjacent prototype: solid-state storage device integrated into a fuel-cell forklift module

**Title:** Optimisation design of solid-state hydrogen storage device for fuel cell forklift

- **Authors/organisation:** J. Ye et al.

- **Venue/type:** Peer-reviewed engineering paper (Journal of Alloys and Compounds)

- **Date:** January 2024

- **Link:** <https://www.sciencedirect.com/science/article/abs/pii/S0925838823035454>

- **Why it matters:** Reports an optimised solid-state storage device with **1.5 kg effective H<sub>2</sub> capacity, 97.6% refuelling completion within 30 min**, and confirmed forklift operation for **~6 hours** under rated conditions—clear evidence of application-level integration beyond laboratory canisters. [11]

#### US government-funded plan for a mobile metal-hydride refuelling system and multi-site fabrication

**Title:** Metal Hydride-Based Hydrogen Storage Supporting Onsite Hydrogen Infrastructure at WGL/Washington Gas

- **Authors/organisation:** U.S. Department of Energy [12] (NEPA determination memo)

- **Venue/type:** Authoritative government project documentation (NEPA categorical exclusion memo)

- **Date:** June 2024

- **Link:** <https://www.energy.gov/sites/default/files/2024-09/CX-031126.pdf>

- **Why it matters:** Documents federal funding to GKN Hydrogen [13] to **design, fabricate, and test a mobile hydrogen refuelling system**, including metal-hydride alloy loading in Bruneck [14] and assembly/testing in Carlsbad [15], followed by a two-year demonstration—strong maturity evidence that prototype-to-demonstration pathways are being executed with real infrastructure sites. [16]

#### Megawatt-scale demonstration platform with ~500 kg class metal-hydride storage commissioned

**Title:** Heavy Metal Debut: A World-Class Metal Hydride System

- **Authors/organisation:** National Renewable Energy Laboratory [17]

- **Venue/type:** National lab feature story describing commissioned demonstration (authoritative institutional publication)

- **Date:** November 2024 (last updated January 2026)

- **Link:** <https://www.nrel.gov/news/detail/program/2024/heavy-metal-debut-a-world-class->

metal-hydride-system

- **Why it matters:** States a commissioned demonstration at the lab's Flatirons Campus integrating an electrolyser (~**1.25 MW PEM**) and a fuel cell (~**1 MW PEM**) with a metal-hydride system storing **up to ~500 kg H<sub>2</sub>**, signalling tangible scaling to hundreds-kg class storage modules and system integration testing. [18]

**DOE Annual Merit Review slide deck: large-scale hydride mega-tank validation plan -**

**Title:** High Efficacy Validation of Hydride Mega Tanks at the ARIES Lab ("HEVHY METAL")

- **Authors/organisation:** National Renewable Energy Laboratory [17] (project presentation)

- **Venue/type:** Authoritative government programme review presentation (DOE Hydrogen Program Annual Merit Review, 2022)

- **Date:** June 2022

- **Link:**

[https://www.hydrogen.energy.gov/docs/hydrogenprogramlibraries/pdfs/review22/ta063\\_christensen\\_2022\\_p.pdf](https://www.hydrogen.energy.gov/docs/hydrogenprogramlibraries/pdfs/review22/ta063_christensen_2022_p.pdf)

- **Why it matters:** Lays out a structured plan and milestones for validating charge/discharge rates and capacity for **~520 kg H<sub>2</sub>** class metal-hydride storage integrated with megawatt-scale infrastructure, which supports maturity assessment via formal programme milestones and validation criteria. [19]

**Vendor technical doc: containerised HY2 product suite and safety claims - Title:**

Hydrogen Solid State Storage (presentation)

- **Authors/organisation:** Vendor technical doc by GKN Hydrogen [13] (hosted by Italian fire safety site)

- **Venue/type:** Vendor technical doc (presentation with measurable specifications)

- **Date:** November 2022

- **Link:** <https://www.vigilfuoco.it/sites/default/files/2024-07/7.%2015112022%20-%20GKN%20%20-%20GRUBER.pdf>

- **Why it matters:** Presents a product suite (HY2MINI/HY2MEDI/HY2MEGA) with stated storage quantities (e.g., **25 kg, 60 kg, 120 kg**, and a case study scale of **500 kg H<sub>2</sub>**) and emphasises low-pressure operation and self-limiting release as safety features; useful as maturity signal but should be treated cautiously as vendor-optimistic. [20]

**Techno-economic and lifecycle evidence for scaled systems**

**LCA of the HyCARE large-scale solid-state storage prototype - Title:** Life cycle assessment for the determination of the environmental impacts of an advanced large-scale hydrogen storage system from HyCARE EU project

- **Authors/organisation:** E. S. Alves et al.

- **Venue/type:** Peer-reviewed applied study (Journal of Cleaner Production)

- **Date:** July 2025

- **Link:** <https://www.sciencedirect.com/science/article/pii/S0959652625011862>

- **Why it matters:** Uses a functional unit of **storing 46 kg H<sub>2</sub> over 50 years** for an advanced HyCARE storage concept and compares configurations (with/without PCM; vs gaseous tube storage), evidencing that the field is progressing into engineering trade-offs and lifecycle considerations typical of post-prototype decision-making. [21]

**Startup/government feasibility evidence for cryo-adsorption monoliths**

**UK feasibility report claiming high volumetric cryo-adsorption capacities in monolithic MOFs (pre-commercial) - Title:** Immaterial – Phase 1 Feasibility Study Report (Monolithic MOFs for enhanced cryo-adsorbed hydrogen storage)

- **Authors/organisation:** Immaterial[22] (client: UK government department)

- **Venue/type:** Government-commissioned feasibility report / technical study (public report; not peer-reviewed)

- **Date:** October 2022

- **Link:**

[https://assets.publishing.service.gov.uk/media/64678f5143fe01000cac65e2/HYS2117\\_Immaterial\\_Final\\_Feasibility\\_Report\\_Public\\_.pdf](https://assets.publishing.service.gov.uk/media/64678f5143fe01000cac65e2/HYS2117_Immaterial_Final_Feasibility_Report_Public_.pdf)

- **Why it matters:** Reports monolithic MOF results such as **45 g/L at 25 bar and 77 K** (Gen 1) and **59 g/L at 100 bar and 77 K** (Gen 2), and describes an initial demonstrator design concept for a **6 kg H<sub>2</sub>** tank; credibility is limited by non-peer-review but still useful for maturity signals about targeted demonstrators and performance targets. [23]

### **Maturity score (1–7) and reasoning**

**Final maturity score: 4**

#### **Justification mapped to the rubric**

#### **Why the evidence rules out levels 1–2 (theory-only / lab principle only):**

Multiple peer-reviewed experimental papers demonstrate both (a) material-level reversible storage performance and (b) engineering near the device level: high-entropy alloys with reversible room-temperature operation and long cycling, plus multiple metal-hydride tank/device papers and demonstrations. [24]

#### **Why the evidence rules out level 3 (lab prototype only):**

There is clear evidence of **functional prototype systems** integrated into realistic application contexts:

- A containerised metal-hydride storage prototype (HyCARE) specifying storage mass, pressure/temperature bounds, and risk management/safety barriers. [10]
- A solid-state storage device integrated into a fuel-cell forklift power module with measured refuelling completion time and operational duration. [11]
- A commissioned **hundreds-kg class** metal-hydride demonstration at a national lab site integrated with megawatt-scale hydrogen infrastructure (electrolyser + fuel cell). [25]

Together these exceed “laboratory prototype” and satisfy the rubric’s requirement for a demonstrable system that can meet functional requirements of intended applications.

#### **Why level 4 fits (PoC demonstrated with viability signals):**

Level 4 requires a functional PoC that meets commercialisation requirements in functionality/viability for production, or plausibly lower cost at scale. The dossier shows:

- Engineering prototypes with defined operating envelopes and safety/risk controls (HyCARE). [26]
- Large-scale validation plans and commissioning within real infrastructure contexts (DOE Annual Merit Review milestones; national lab commissioning). [27]
- Manufacturing and supply-chain signals (industrial-level alloy batch production; extrusion/pelletisation approaches; DOE-funded fabrication/testing across multiple sites). [28]

These collectively justify “PoC” status for the **metal-hydride system variant** and show narrowing of major blockers (heat management, safety, manufacturability pathways).

#### **What is still missing to justify level 5 or higher:**

To reach level 5–6, the evidence would need stronger, verifiable signals of **repeatable product deployment at scale**, such as:

- multiple independent, well-capitalised competitors shipping comparable systems in meaningful volume,
- multi-year field performance datasets (cycle life under real duty cycles; impurity exposure; maintenance costs),
- certification/C&S milestones (type approvals, codes & standards adoption specific to these modules),
- and clear evidence of scaled manufacturing investment translating into deliveries and unit cost trajectories.

The current evidence is dominated by demonstrations, feasibility studies, and early product-suite claims rather than documented high-volume customer deliveries. [29]

#### **Sub-scores and aggregation (bundle reasoning)**

##### **Reversible metal-hydride storage modules (systems + tanks): maturity ≈ 4–5**

- Strongest evidence: containerised HyCARE prototype (40 kg H<sub>2</sub> at <50 bar, <100 °C) and national-lab commissioning of ~500 kg class metal-hydride system integrated with megawatt infrastructure. [30]
- Supporting evidence: forklift-integrated solid-state storage device and government-funded mobile refuelling system plan. [31]
- Interpretation: Functionality and integration appear PoC-level (4), with some signs of scaling and productisation (pushing toward 5), but not enough verified volume deployment.

##### **Porous adsorbent cryo-adsorption storage (MOFs/ZIFs with shaping): maturity ≈ 3–4**

- Strongest evidence: peer-reviewed densified monoliths (high volumetric H<sub>2</sub> metrics) and pelletised ZIF-8 demonstrating reproducible uptake and a usable-capacity framing; inter-lab reference-material study reduces measurement uncertainty—critical for standardisation and commercial claims. [32]
- Feasibility evidence: UK feasibility report claims 45–59 g/L monolith capacities and outlines a route to a 6 kg H<sub>2</sub> demonstrator, but remains non-peer-review and thus a weaker maturity signal. [33]
- Interpretation: Material and shaping advances are strong, but system-level deployment (particularly with cryogenic balance-of-plant) appears earlier than metal hydrides.

#### **Aggregation to one ART score:**

Because the ART description covers both **metal hydrides** and **porous adsorbents** serving the same overall function (solid(ish) hydrogen storage with safer form factors), the overall maturity is best treated as an **average weighted toward the more deployment-proximate hydride systems**, yielding **Score 4**. [34]

## Group 8 - Energy Generation, Storage & Conversion

### ART 08.056 Fusion Energy Reactors

#### ART extraction

#### Parsed ART claims

##### A) Primary capability (what the ART claims it can do)

- Deliver a controllable, continuously operating fusion heat source (and ultimately electricity or high-temperature process heat) from light-isotope fuels, with no combustion emissions and relatively small volumes of long-lived waste (as described in the ART).
- Operate as an industrial facility with dense diagnostics, fast feedback control, shielding, and remote/robotic maintenance in “hot” (high-radiation) environments (as described in the ART).

##### B) Key sub-components / variants (sub-threads of the bundle)

- **Magnetic confinement:** tokamaks and stellarators (plasma shaping, heating, and control).
- **Inertial confinement / inertial fusion energy (IFE):** laser-driven implosions (indirect drive and direct drive), plus the repetition-rate and target-supply engineering needed for power production. [1]
- **High-field magnet technology:** high-temperature superconductors (HTS), demountable joints, cryogenics, quench detection/protection. [2]
- **Plasma sensing + fast control:** real-time control systems, advanced control methods (including machine learning) that can handle high-dimensional plasma shaping and constraints. [3]
- **Neutron-tolerant materials / components:** reduced-activation structural steels, plasma-facing components/divertors, irradiation hardening/embrittlement and lifetime under reactor conditions. [4]
- **Fuel cycle:** tritium breeding blankets, tritium handling and accountancy, startup tritium inventory constraints, safety and safeguards interfaces. [5]

- **Remote handling / hot-cell-style maintenance:** remotely controlled tools, connectors, and workflows for rapid component replacement to support high availability. [6]

### C) “Maturity indicators” that would count as evidence for this ART

- **Physics plausibility:** experimentally demonstrated ignition/burning-plasma milestones (IFE), and reactor-relevant D-T plasma behaviour/validation (magnetic confinement). [7]

- **Engineering plausibility:** long-pulse, actively cooled plasma-facing components and heat-exhaust control; validated high-field magnet prototypes at representative scale; demonstrated remote maintenance prototypes and procedures. [8]

- **Path-to-market maturity:** credible pilot-plant/demonstration planning by major public programmes; identifiable regulatory pathway; and proof that key bottlenecks (materials lifetime, tritium self-sufficiency, availability/uptime) are moving from “known unknowns” to demonstrated solutions. [9]

### Evidence (10–20 recent, reliable sources)

1) **Title:** Achievement of Target Gain Larger than Unity in an Inertial Fusion Experiment

**Authors/organisation:** H. Abu-Shawareb[10] et al. (Indirect Drive ICF Collaboration; reported via Lawrence Livermore National Laboratory[11] / National Ignition Facility[12] records)

**Venue/type:** Peer-reviewed paper (Physical Review Letters; indexed by OSTI)

**Publication date:** February 2024

**Link (URL):** <https://www.osti.gov/biblio/2283994>

**Why it matters (1–2 sentences):** Reports a NIF implosion (5 Dec 2022) with **target gain ~1.5**, where **2.05 MJ** of laser energy produced **~3.1 MJ** fusion yield—an unequivocal physics plausibility milestone (scientific breakeven at the target). [13]

2) **Title:** Demonstration of hot-spot fuel gain exceeding unity in direct-drive inertial confinement fusion implosions

**Authors/organisation:** C. A. Williams[14] et al.

**Venue/type:** Peer-reviewed paper (Nature Physics)

**Publication date:** 5 February 2024 (version of record; issue date May 2024)

**Link (URL):** <https://www.nature.com/articles/s41567-023-02363-2>

**Why it matters (1–2 sentences):** Demonstrates **hot-spot fuel gain > 1** in **direct-drive** ICF, strengthening plausibility that non-indirect-drive schemes can reach burning-plasma-relevant regimes and offering a second, independent experimental track toward IFE concepts. [15]

3) **Title:** Future for inertial-fusion energy in Europe: a roadmap

**Authors/organisation:** Dimitri Batani[16] et al.

**Venue/type:** Peer-reviewed review / roadmap (High Power Laser Science and Engineering)

**Publication date:** Published online 28 September 2023

**Link (URL):** <https://www.cambridge.org/core/journals/high-power-laser-science-and-engineering/article/future-for-inertialfusion-energy-in-europe-a-roadmap/CA1BC0917BDCF29906B9D30799D945E9>

**Why it matters (1–2 sentences):** Converts recent ignition milestones into an engineering-centred European roadmap, explicitly identifying power-plant-relevant gaps such as **high-repetition-rate**, **high-energy lasers**, target supply, and supporting infrastructure—evidence that IFE is plausible but still far from plant-class maturity. [17]

4) **Title:** Overview of T and D–T results in JET with ITER-like wall

**Authors/organisation:** C. F. Maggi[18] et al. (JET Contributors)

**Venue/type:** Peer-reviewed paper (Nuclear Fusion; open access PDF via institutional repository)

**Publication date:** November 2024 (issue information indicates 01.11.2024)

**Link (URL):**

[https://research.chalmers.se/publication/543057/file/543057\\_Fulltext.pdf](https://research.chalmers.se/publication/543057/file/543057_Fulltext.pdf)

**Why it matters (1–2 sentences):** Synthesises reactor-relevant **T and D-T** campaigns with an ITER-like Be/W wall, including goals such as sustaining **≥10 MW fusion power for 5 s**, and documenting achieved records such as **59 MJ** sustained D-T fusion energy (recorded as “new world record” in the paper’s conclusions). [19]

5) **Title:** Overview of deuterium-tritium nuclear operations at JET

**Authors/organisation:** R. Villari[20] et al.

**Venue/type:** Peer-reviewed paper (Fusion Engineering and Design; open access)

**Publication date:** August 2025 (Volume 217)

**Link (URL):**

<https://www.sciencedirect.com/science/article/pii/S0920379625003308>

**Why it matters (1–2 sentences):** Frames JET as an integrated **nuclear tokamak** testbed: two DT campaigns (2021 and 2023) produced **>1.5×10<sup>21</sup>** 14.1 MeV neutrons and generated data for **activation, materials damage, water activation, electronics effects**, and **licensing-relevant** benchmarking—evidence of progression from plasma physics toward plant-adjacent nuclear engineering questions. [21]

6) **Title:** Overview of the first Wendelstein 7-X long-pulse campaign with fully water-cooled plasma facing components

**Authors/organisation:** O. Grulke[22] et al. (device: Wendelstein 7-X[23])

**Venue/type:** Peer-reviewed paper (Nuclear Fusion)

**Publication date:** 15 August 2024

**Link (URL):**

[https://acris.aalto.fi/ws/portalfiles/portal/162804594/Overview\\_of\\_the\\_first\\_Wendelstein\\_7-X\\_long\\_pulse\\_campaign\\_with\\_fully\\_water-cooled\\_plasma\\_facing\\_components.pdf](https://acris.aalto.fi/ws/portalfiles/portal/162804594/Overview_of_the_first_Wendelstein_7-X_long_pulse_campaign_with_fully_water-cooled_plasma_facing_components.pdf)

**Why it matters (1–2 sentences):** Reports a long-pulse, actively cooled campaign with **up to 480 s (8 min)** discharge length and **~1.3 GJ** total heating energy, demonstrating (a) the practicality of extensive water-cooling of plasma-facing components and (b) controlled divertor heat-exhaust scenarios—key precursors for steady-state reactor operation. [24]

7) **Title:** Recent progress of JT-60SA project toward plasma operation

**Authors/organisation:** H. Shirai[25] et al. (device: JT-60SA[26]; joint Japan–Euratom Broader Approach)

**Venue/type:** Peer-reviewed paper (Nuclear Fusion)

**Publication date:** 2024 (paper file indicates Nuclear Fusion 64 (2024) 112008)

**Link (URL):**

[https://acris.aalto.fi/ws/portalfiles/portal/162313809/Recent\\_progress\\_of\\_JT-60SA\\_project\\_toward\\_plasma\\_operation.pdf](https://acris.aalto.fi/ws/portalfiles/portal/162313809/Recent_progress_of_JT-60SA_project_toward_plasma_operation.pdf)

**Why it matters (1–2 sentences):** Documents superconducting-tokamak commissioning and risk-mitigation engineering (e.g., insulation reinforcement, voltage-to-ground reductions,

improved interlocks), and records first plasma milestones (e.g., first plasma achieved 23 Oct 2023) as an ITER-relevant operational learning platform. [27]

8) **Title:** Updated baseline presented (34th ITER Council)

**Authors/organisation:** ITER Organization[28]

**Venue/type:** Authoritative programme update (official project baseline status)

**Publication date:** 20 June 2024

**Link (URL):** <https://www.iter.org/node/20687/updated-baseline-presented>

**Why it matters (1–2 sentences):** Provides schedule-grade maturity evidence for the leading magnetic-confinement flagship: the proposed baseline includes **deuterium-deuterium fusion operation in 2035** and explicitly frames re-baselining around **licensing and technical risk reduction**—a candid view of time-to-scale constraints. [29]

9) **Title:** ITER progresses into new baseline

**Authors/organisation:** Pietro Barabaschi[30] et al. (“ITER Contributors”)

**Venue/type:** Peer-reviewed / programme paper (Fusion Engineering and Design)

**Publication date:** June 2025 (Volume 215)

**Link (URL):**

<https://www.sciencedirect.com/science/article/abs/pii/S0920379625001905>

**Why it matters (1–2 sentences):** Captures an engineering-management and integration view of ITER’s revised baseline in a citable technical venue, reinforcing that large-scale fusion programmes are still in a risk-reduction phase rather than a plant-replication phase. [31]

10) **Title:** Balance of plant conceptual design of EU DEMO integrating different breeding blanket concepts

**Authors/organisation:** Matteo Zaupa[32] et al.

**Venue/type:** Peer-reviewed paper (Fusion Engineering and Design; open access)

**Publication date:** March 2024 (Volume 200)

**Link (URL):**

<https://www.sciencedirect.com/science/article/pii/S0920379624000887>

**Why it matters (1–2 sentences):** Treats the fusion plant as a whole system: explicitly targets “**several hundred MWs of net electricity**” and analyses how different tritium-breeding blanket choices cascade into balance-of-plant and power-conversion design, evidencing that DEMO-class work is active but remains conceptual. [33]

11) **Title:** Replacement strategy of the EU-DEMO and CFETR breeding blanket pipes

**Authors/organisation:** Rocco Mozzillo[34] et al.

**Venue/type:** Peer-reviewed paper (Fusion Engineering and Design; open access)

**Publication date:** May 2024 (Volume 202)

**Link (URL):**

<https://www.sciencedirect.com/science/article/pii/S0920379624001649>

**Why it matters (1–2 sentences):** Quantifies a major availability bottleneck: for blanket maintenance, **320 pipes** would need to be cut/removed/rewelded, and the paper reports progress toward **manufactured prototypes** and dedicated test benches (including collaboration with China’s CRAFT/ASIPP) intended to reduce downtime. [35]

12) **Title:** Impact of neutron irradiation on the tensile properties of advanced EUROFER97-type steels

**Authors/organisation:** O. Kachko[36] et al.

**Venue/type:** Peer-reviewed paper (Journal of Nuclear Materials; ScienceDirect record)

**Publication date:** 2024 (month not shown in the accessible abstract record)

**Link (URL):**

<https://www.sciencedirect.com/science/article/abs/pii/S0022311524002782>

**Why it matters (1–2 sentences):** Addresses a central feasibility constraint for D-T fusion: irradiation hardening and embrittlement of RAFM steels (EUROFER97) under relevant temperature windows (noted challenges below ~350 °C), directly linking neutron exposure to reduced ductility/toughness—evidence that materials lifetime remains a key maturity limiter. [37]

13) **Title:** UK Fusion Materials Roadmap 2.0

**Authors/organisation:** UK Atomic Energy Authority[38] (roadmap document)

**Venue/type:** Authoritative roadmap/report (national fusion materials roadmap)

**Publication date:** September 2025 (published file timing and document framing as “Roadmap 2025”)

**Link (URL):** <https://www.ukaea.org/wp-content/uploads/2025/09/uk-materials-roadmap-2-0.pdf>

**Why it matters (1–2 sentences):** Consolidates plant-readiness “gap lists” across magnets/shielding, tritium breeding, high-temperature and radiation-hardened materials, and explicitly states that D-T plants must breed tritium but practical routes (materials selection, barriers/coatings, retention) remain unresolved and require coordinated testing infrastructure. [39]

14) **Title:** Investigating the application of Kalman Filters for real-time accountancy in fusion fuel cycles

**Authors/organisation:** H. B. Flynn[40]; George Larsen

**Venue/type:** Peer-reviewed paper (Fusion Engineering and Design)

**Publication date:** March 2022 (Volume 176)

**Link (URL):**

<https://www.sciencedirect.com/science/article/pii/S0920379622000370>

**Why it matters (1–2 sentences):** Focuses on a concrete “fusion plant operations” requirement—**tritium accountancy** under continuous operation and noisy measurements—and demonstrates modelling/estimation methods (Kalman filtering) aimed at meeting stringent inventory tracking; this underlines that fuel-cycle instrumentation and state estimation are active R&D, not solved commodities. [41]

15) **Title:** The SPARC Toroidal Field Model Coil Program

**Authors/organisation:** Zachary Hartwig[42] et al. (MIT PSFC / CFS programme; device pathway toward SPARC[43])

**Venue/type:** Preprint with substantial engineering detail (arXiv)

**Publication date:** August 2023 (arXiv submission year; exact posting date not required for window compliance)

**Link (URL):** <https://arxiv.org/abs/2308.12301>

**Why it matters (1–2 sentences):** Reports representative-scale HTS magnet testing with quantitative performance: **20.1 T peak field-on-conductor**, **40.5 kA** terminal current, and demountable joints operating in the **~0.5–2.0 nΩ** range at **20 K**—strong plausibility evidence for compact high-field magnetic confinement approaches. [44]

16) **Title:** Development of a high current density, high temperature superconducting cable for pulsed magnets

**Authors/organisation:** Charlie Sanabria[45] et al.

**Venue/type:** Peer-reviewed paper (Superconductor Science and Technology; indexed by OSTI)

**Publication date:** 23 September 2024

**Link (URL):** <https://www.osti.gov/pages/biblio/2447881>

**Why it matters (1–2 sentences):** Provides an HTS “supply-chain-ready” advancement for fusion magnets (REBCO cable technology for pulsed magnets), supporting maturation of one of the most capital-intensive and schedule-critical subsystems for magnetic fusion reactors. [46]

17) **Title:** Development of the optical remote handling connector for ITER Divertor Operational Instrumentation

**Authors/organisation:** Janne Lyytinen[47] et al.

**Venue/type:** Peer-reviewed paper (Fusion Engineering and Design; open access)

**Publication date:** September 2023 (Volume 194)

**Link (URL):**

<https://www.sciencedirect.com/science/article/pii/S0920379623003186>

**Why it matters (1–2 sentences):** Demonstrates plant-style maintainability engineering: designs and **tests a full-size mock-up** remote-handling connector under **high-vacuum ( $\sim 10^{-5}$  Pa), high-temperature (up to 350 °C), and high radiation dose (up to 1 GGy)** constraints, including industrial manipulator connect/disconnect trials—direct evidence of progress toward robotic maintenance in hazardous environments. [48]

18) **Title:** Magnetic control of tokamak plasmas through deep reinforcement learning

**Authors/organisation:** Jonas Degraeve[49] et al.

**Venue/type:** Peer-reviewed paper (Nature)

**Publication date:** 16 February 2022

**Link (URL):** <https://www.nature.com/articles/s41586-021-04301-9>

**Why it matters (1–2 sentences):** Shows a credible pathway to the ART’s “fast control + digital twin” operating style: a controller architecture that can autonomously learn to command a plasma’s magnetic control coils under constraints, reducing design effort for new configurations—relevant to future high-availability operations where control complexity scales up. [50]

19) **Title:** Regulatory Framework for Fusion Systems (availability of preliminary proposed rule language; public meeting)

**Authors/organisation:** U.S. Nuclear Regulatory Commission[51] (Federal Register notice)

**Venue/type:** Authoritative regulatory document (Federal Register)

**Publication date:** 4 October 2023

**Link (URL):** <https://www.federalregister.gov/documents/2023/10/04/2023-21988/regulatory-framework-for-fusion-systems>

**Why it matters (1–2 sentences):** Establishes a concrete near-term licensing pathway: NRC is considering amendments to its **byproduct material** regulations (10 CFR Parts 20/30/51) to create a technology-inclusive fusion regulatory framework, responding to NEIMA’s direction to establish a framework by **31 Dec 2027**—a key maturity prerequisite for commercial deployment. [52]

20) **Title:** Fusion Energy Strategy 2024

**Authors/organisation:** U.S. Department of Energy[\[53\]](#)

**Venue/type:** Authoritative strategy/roadmap report (government programme strategy)

**Publication date:** June 2024

**Link (URL):** <https://www.energy.gov/sites/default/files/2024-06/fusion-energy-strategy-2024.pdf>

**Why it matters (1–2 sentences):** Provides explicit maturity framing: targets private-sector-led fusion pilot plants in the **2030s** and highlights “commercialisation risks” such as **materials**, **supply chains**, and **fuel isotopes**, including the need for **startup tritium and lithium-6** even if plants ultimately breed their own tritium. [\[54\]](#)

**Maturity score (1–7) and reasoning**

**Final maturity score**

**Final maturity score: 3**

**Evidence-to-rubric mapping**

**What evidence rules out levels 1–2 (i.e., why this is beyond “principle verified”)?**

- Multiple subthreads have moved past theoretical plausibility into **repeatable laboratory and facility-scale demonstrations** of key enabling functions:
- IFE has peer-reviewed demonstrations of **energy gain metrics exceeding unity** (target gain at NIF; hot-spot fuel gain in direct-drive). [\[55\]](#)
- Magnetic fusion has reactor-relevant **D–T operational campaigns** with ITER-like wall materials, documented in a recent peer-reviewed synthesis (JET) and a nuclear-operations engineering overview (activation, materials damage, benchmarking for licensing). [\[56\]](#)
- Stellarator development has crossed an engineering threshold for long-pulse operations with **fully water-cooled plasma-facing components** and substantial delivered energy over minutes, directly addressing the shift from “short physics shots” to “thermally managed operation.” [\[24\]](#)
- High-field magnet technology has been demonstrated at representative scale with quantified performance (20.1 T class HTS coil) and parallel work on manufacturable HTS cables. [\[2\]](#)

These collectively meet the rubric’s Level-3 condition: **laboratory / facility prototypes show previously blocking problems are being solved in practice**, though cost, durability, and integrated plant operability are not yet proven at scale. [\[57\]](#)

**What evidence is still missing to justify Level 4 (PoC meeting commercialisation requirements)?**

Level 4 would require an integrated prototype that convincingly meets commercialisation requirements (continuous high-duty operation, practical heat extraction and power conversion, fuel sustainability, and maintainability/availability). The evidence set still shows major gaps:

- **Plant-integrated power production and availability** remain largely conceptual or programme-planned: EU DEMO balance-of-plant work is explicitly “conceptual design,” and ITER timelines place D-D operation in **2035**, underscoring distance from commercial PoC. [\[58\]](#)
- **Materials lifetime under fusion neutron spectra** is still a limiting uncertainty, with recent

work emphasising irradiation-induced hardening/embrittlement challenges in key candidate structural steels. [4]

- **Tritium self-sufficiency** is not yet demonstrated in an operating fusion machine; authoritative strategy documents emphasise the need for **startup tritium** and staged closure of fuel-cycle gaps, and technical work continues on high-fidelity tritium accountancy methods. [59]

- **Remote maintenance at plant scale** is progressing (e.g., full-size connector mock-ups and DEMO blanket pipe maintenance concepts with prototypes), but these are still subsystem validations rather than integrated, high-availability plant demonstrations. [60]

- **Regulatory pathways** are emerging (e.g., NRC rulemaking activity), but broad, internationally harmonised fusion licensing practice and standardised safety cases are not yet “routine,” which is typically needed before PoC-to-product transitions. [61]

Given these gaps, the whole ART cannot credibly be scored as Level 4+ today: the sector has **strong prototypes and fast progress**, but it is not yet at “commercialisation-requirements-met” PoC for an electricity-producing, tritium-self-sufficient fusion plant. [62]

### Sub-component breakdown and aggregation

Because “fusion energy reactors” is a bundled ART with heterogeneous maturity across subsystems, the score is best treated as an **average-weighted plant readiness** rather than the maximum of any one subthread.

- **Inertial confinement fusion (physics milestone subthread) → 3**
- Target/physics energy-gain milestones are experimentally demonstrated, but a power-plant-relevant repetition-rate system and target supply chain are explicitly future work in roadmaps. [63]
- **Magnetic confinement plasma + nuclear operations → 3**
- Reactor-relevant D-T operations and nuclear engineering benchmarking exist, but ITER’s schedule and ongoing baseline revisions indicate remaining integration and risk-reduction work before pilot-plant-like operations. [64]
- **Stellarator long-pulse, actively cooled PFCs → 3**
- Minutes-scale discharges with water-cooled components are a major step, but still below steady-state commercial duty cycles and without a full power-plant fuel cycle. [24]
- **HTS magnets and superconducting infrastructure → 3**
- Representative-scale, quantified coil demonstrations and cable developments exist, but fleet manufacturing and long-life under reactor neutron environments remain to be proven for power-plant deployment. [65]
- **Fuel cycle (tritium) and breeding blankets → 2–3**
- The need for startup tritium and the difficulty of accountancy and self-sufficiency are explicitly recognised in authoritative strategy and technical studies, while DEMO/blanket maintenance shows design/prototype activity rather than operational closure. [66]

- **Remote handling / maintainability engineering → 3 (with some elements approaching 4)**
- Full-size mock-ups and maintenance concepts with prototypes exist (connectors; blanket pipe handling), but not yet as an integrated “plant turnaround” system proven under full nuclear conditions and commercial availability targets. [60]

**Aggregation rationale:** The strongest components (plasma physics milestones, long-pulse cooled operation, and HTS magnet prototypes) justify Level 3, but fuel-cycle closure, materials lifetime, and plant-level availability still anchor the overall ART below Level 4. This supports a single overall score of **3** rather than a maximum-based 4+. [67]

## ART 08.057 Small Modular Fission Reactors (SMRs)

151. ART extraction

### Primary capability claimed (1–3 bullets)

- Deliver **firm, high-density nuclear electricity** in smaller, repeatable units (tens to a few hundreds of MWe) rather than bespoke gigawatt-scale megaprojects.
- **Reduce construction risk and schedule** via standardised designs, factory fabrication of major components, and modular delivery/assembly.
- Improve safety and operability using **passive / inherent safety features** (e.g., natural circulation, gravity-fed cooling), plus high instrumentation and remote-support operations.

### Key sub-components / variants (3–7 sub-threads)

- **Light-water SMRs (LWR-SMRs)**: integral PWRs and natural-circulation BWRs (closest to existing nuclear industrial base).
- **Non-light-water “advanced” SMRs**: high-temperature gas-cooled reactors (HTGRs), sodium-cooled fast reactors, molten-salt concepts (often more dependent on novel fuels/supply chains).
- **Passive decay-heat removal architectures**: isolation condensers, passive containment cooling, natural circulation loops, gravity-driven injection, etc.
- **Manufacturing & modular construction**: heavy forgings, nuclear-grade QA, repeatable module fabrication, transport logistics, site assembly.
- **Licensing/regulatory pathways**: design certification/approval, construction licence issuance, generic design assessments, multi-jurisdiction harmonisation efforts.
- **Fuel supply & back-end**: conventional LEU for many LWR-SMRs; **HALEU** (5–20% enrichment) for many advanced SMRs; spent-fuel handling, storage, and ultimate disposal.
- **Digital operations**: instrumentation, diagnostics, cyber-secure remote monitoring, and “digital twin”/model-based planning (varies by design and regulator acceptance).

### What “maturity evidence” should look like for this ART

- **Regulatory milestones**: design certification/approval and/or **construction licences** granted for FOAK projects; progressing generic assessments.
- **Project execution evidence**: site permits, EPC contracting, long-lead procurement, first nuclear concrete, module manufacturing milestones.
- **Supply-chain readiness**: qualified nuclear-grade manufacturing capacity; standards/codes maturity; evidence of repeatable QA processes.
- **Fuel readiness**: secured fuel pathways (LEU or HALEU) with credible timelines and licensed facilities.
- **Operational readiness**: staffing/remote-support concepts accepted by regulators; credible cybersecurity and instrumentation approaches.
- **Commercial traction**: multiple well-capitalised vendors and utilities moving beyond studies towards financed builds and repeat orders.

### Evidence (10–20 recent, reliable sources)

152. Evidence (10–20 recent, reliable sources)

### Evidence selection notes

All sources below have a visible publication date (or “last updated/modified” date) within the strict window **February 2022–February 2026**. The set is intentionally weighted toward **regulators, national agencies, and technical programme documents** because those best evidence market proximity (licensing, construction authority, supply-chain constraints) for nuclear fission deployments.

### Annotated source list

#### 1) NuScale Small Modular Reactor Design Certification

Organisation: U.S. Nuclear Regulatory Commission[1]

Venue/type: Regulatory final rule (Federal Register)

Publication date: **January 2023** (effective **February 2023**)

Link: <https://www.federalregister.gov/documents/2023/01/19/2023-00729/nuscale-small-modular-reactor-design-certification>

Annotation: The rule **certifies the NuScale standard SMR design**, enabling future applicants to reference the certified design in licensing applications—strong evidence that an SMR design has crossed major safety and regulatory review thresholds. This directly supports technical plausibility and shows maturity beyond prototype-only status. [2]

#### 2) NuScale Power, LLC; NuScale US460 Small Modular Reactor; Standard Design Approval

Organisation: U.S. Nuclear Regulatory Commission

Venue/type: Regulatory notice (Federal Register)

Publication date: **June 2025** (SDA issued **May 2025**)

Link: <https://www.federalregister.gov/documents/2025/06/04/2025-10123/nuscale-power-llc-nuscale-us460-small-modular-reactor-standard-design-approval>

Annotation: Confirms NRC issuance of a **Standard Design Approval (SDA)** allowing the NuScale US460 SMR design to be referenced in construction/operating licence applications, and notes completion of NRC staff technical review (FSER). This is high-grade maturity evidence for an LWR-SMR pathway. [3]

#### 3) Standard Design Approval for the NuScale US460 Power Plant Design (approval letter + enclosed SDA)

Organisation: NuScale Power, LLC[4]

Venue/type: Regulator letter + approval documentation (official PDF)

Publication date: **May 2025**

Link:

[https://content.govdelivery.com/attachments/USNRC/2025/05/29/file\\_attachments/3275315/Standard%20Design%20Approval%20SDA%20for%20the%20NuScale%20US460%20Power%20Plant%20Design.pdf](https://content.govdelivery.com/attachments/USNRC/2025/05/29/file_attachments/3275315/Standard%20Design%20Approval%20SDA%20for%20the%20NuScale%20US460%20Power%20Plant%20Design.pdf)

Annotation: Provides concrete regulatory details: the US460 design is **~250 MWt / 77 MWe per module** and the SDA is valid **15 years**, and states that issuance signifies completion of NRC technical review. This directly evidences “design frozen + regulator-reviewed” maturity rather than a lab or paper concept. [5]

#### 4) Combined phases 1 and 2 pre-licensing vendor design review – GEH Nuclear Energy (executive summary)

Organisation: Canadian Nuclear Safety Commission[6]

Venue/type: Regulator pre-licensing design review summary report

Publication date: **March 2023** (date modified shown)

Link: <https://www.cnsccsn.gc.ca/eng/reactors/power-plants/pre-licensing-vendor-design-review/geh-nuclear-energy-executive-summary/>

Annotation: CNSC reports reviewing **200+ design documents** and concludes the vendor understands regulatory requirements and that CNSC staff did **not identify fundamental barriers to licensing**, while listing remaining technical areas (e.g., severe-accident analysis, decommissioning programme detail). This is strong evidence of plausibility plus a clear picture of “what remains” before broader deployment. [7]

#### 5) **Commission authorises a construction licence for one BWRX-300 at the Darlington New Nuclear Project**

Organisation: Canadian Nuclear Safety Commission (news release with decision summary)

Venue/type: Regulator decision / construction licence announcement

Publication date: **April 2025**

Link: <https://www.canada.ca/en/nuclear-safety-commission/news/2025/04/commission-authorizes-ontario-power-generation-inc-to-construct-1-bwrx-300-reactor-at-the-darlington-new-nuclear-project-site.html>

Annotation: Announces issuance of a **power reactor construction licence** to Ontario Power Generation Inc.[8] to construct **one** BWRX-300 SMR, including licence validity to **2035** and reference to a public hearing process. A construction licence is among the strongest near-market maturity indicators available for SMRs. [9]

#### 6) **Darlington New Nuclear Project (licensing status overview page)**

Organisation: Canadian Nuclear Safety Commission

Venue/type: Regulator project status page (official)

Publication date: **January 2026** (date modified shown)

Link: <https://www.cnsccsn.gc.ca/eng/reactors/new-reactor-power-plant-projects/new-reactor-power-plant-facilities/darlington-new-nuclear-project/>

Annotation: Consolidates key maturity facts in one regulator source: the project includes **site preparation, construction, and operation** of up to 4 reactors; it confirms the facility now **holds a licence to construct** (valid until **March 2035**) and documents prior licence stages. This supports assessment of real project progression beyond paper licensing. [10]

#### 7) **Generic Design Assessment of the BWRX-300: Step 2 Summary Report**

Organisation: Office for Nuclear Regulation[11]

Venue/type: Regulator generic design assessment report (PDF)

Publication date: **December 2025**

Link: <https://www.onr.org.uk/media/taufoxsv/bwrx-300-gda-step-2-summary-report.pdf>

Annotation: The report describes the BWRX-300 as a **~870 MWth / ~300 MWe** natural-circulation BWR and focuses on novelty such as **advanced construction techniques** and the **isolation condenser system**; it states ONR did **not identify fundamental shortfalls** that would prevent permissioning (subject to future evidence). It also records design claims such as **multi-day passive cooling without power/operator action**, which is central to the ART's passive-safety premise. [12]

#### 8) **GDA Step 2 of the Rolls-Royce SMR: fundamental assessment**

Organisations: Environment Agency[13] and Natural Resources Wales[14]

Venue/type: Regulator publication (GDA Step 2 suite; official government page)

Publication date: **July 2024**

Link: <https://www.gov.uk/government/publications/gda-step-2-of-the-rolls-royce-smr-fundamental-assessment>

Annotation: Documents that the UK regulators completed **Step 2** of Generic Design Assessment for the **Rolls-Royce 470 MWe SMR design**, including a public summary and full report set, and provides the formal timeline (Step 1 began April 2022; Step 2 began April 2023). This is concrete evidence of active, staged licensing progress for another major SMR vendor. [15]

#### 9) **Pathways to Commercial Liftoff: Advanced Nuclear**

Organisation: U.S. Department of Energy [16]

Venue/type: Government roadmap / commercialisation report (PDF)

Publication date: **September 2024**

Link: <https://gain.inl.gov/content/uploads/4/2024/11/DOE-Advanced-Nuclear-Liftoff-Report.pdf>

Annotation: This report explicitly covers **small modular reactors** and frames the pathway from FOAK to NOAK, including “committed orderbook,” “project delivery,” and “industrialization” levers. It is strong evidence that commercial-scale deployment barriers are now dominated by financing, delivery, and industrial base—not basic scientific feasibility. [17]

#### 10) **Final HALEU EIS Summary (DOE/EIS-0559): support for commercial production of HALEU**

Organisation: U.S. Department of Energy

Venue/type: Government environmental impact statement (EIS) summary (PDF)

Publication date: **October 2024**

Link: <https://www.energy.gov/sites/default/files/2024-12/FINAL%20HALEU%20EIS%20Summary.pdf>

Annotation: DOE describes a programme to acquire (via procurement) HALEU enriched **≥19.75% and <20% U-235** over a **10-year** period, including enrichment and deconversion activities—direct evidence that fuel supply is a central gating factor for many advanced SMR variants. It also highlights that follow-on licensing/permits and site-specific analyses are required before facilities operate, reinforcing maturity constraints outside the reactor hardware itself. [18]

#### 11) **The NEA Small Modular Reactor Dashboard: Volume II**

Organisation: OECD Nuclear Energy Agency [19]

Venue/type: International agency assessment / dashboard report (PDF)

Publication date: **July 2023**

Link: [https://www.oecd.org/content/dam/oecd/en/publications/reports/2023/07/the-nea-small-modular-reactor-dashboard\\_c30b50a8/e586e483-en.pdf](https://www.oecd.org/content/dam/oecd/en/publications/reports/2023/07/the-nea-small-modular-reactor-dashboard_c30b50a8/e586e483-en.pdf)

Annotation: Provides a structured global snapshot of progress across **licensing, siting, financing, supply chain, engagement, and fuel** for a set of SMR designs, using verifiable public sources and explicit criteria. This is useful maturity evidence because it evaluates more than “is it buildable”—it tracks real-world readiness dimensions needed for deployment. [20]

### 12) **The NEA Small Modular Reactor Dashboard: Second Edition (overview page + metadata)**

Organisation: OECD Nuclear Energy Agency

Venue/type: International agency publication page (methods + headline counts)

Publication date: **February 2024** (timestamp shown on page metadata)

Link: [https://www.oecd-neo.org/jcms/pl\\_90816/the-nea-small-modular-reactor-dashboard-second-edition](https://www.oecd-neo.org/jcms/pl_90816/the-nea-small-modular-reactor-dashboard-second-edition)

Annotation: Defines SMRs as typically **≤300 MWe** (some 1–10 MWe) and emphasises modular manufacturing/portability/scalability; it states the edition identified **98** SMR technologies and included **56** in the assessment, with a progress cutoff of **10 November 2023**. This evidences a large, competitive development ecosystem—supporting the rubric’s “many well-capitalised actors competing” criterion. [21]

### 13) **Advanced Reactor Codes and Standards Collaborative Workshop: meeting summary & attachments**

Organisation: Electric Power Research Institute[22]

Venue/type: Technical workshop summary (codes/standards; PDF)

Publication date: **November 2023**

Link: [https://arcsc.azurewebsites.net/Files/11-30-23\\_ARCSC\\_Workshop\\_Summary\\_Final\\_w-Attachments%282%29.pdf](https://arcsc.azurewebsites.net/Files/11-30-23_ARCSC_Workshop_Summary_Final_w-Attachments%282%29.pdf)

Annotation: Documents a multi-stakeholder effort (including standards bodies, national labs, and vendors) to close gaps in **consensus codes and standards** for advanced reactors, including SMRs, and notes a compiled list of **~1000** nuclear-related standards/projects. This is direct evidence that non-reactor engineering infrastructure (standards, qualification, conformance) is an active maturity bottleneck being worked in parallel with reactor licensing. [23]

### 14) **TANDEM Deliverable D4.1: status report on safety analysis in Europe from operational flexibility and cogeneration viewpoint**

Organisation: TANDEM project consortium (public deliverable)

Venue/type: Euratom-funded technical report (PDF)

Publication date: **February 2023** (issued **8 March 2023**)

Link: [https://tandemproject.eu/wp-content/uploads/2023/03/TANDEM\\_D4\\_1\\_Status\\_report\\_on\\_safety\\_analysis\\_in\\_Europe\\_from\\_the\\_operational\\_flexibility\\_andcogeneration\\_viewpoint\\_V1.pdf](https://tandemproject.eu/wp-content/uploads/2023/03/TANDEM_D4_1_Status_report_on_safety_analysis_in_Europe_from_the_operational_flexibility_andcogeneration_viewpoint_V1.pdf)

Annotation: Concludes that European studies on safety aspects of integrating **light-water SMRs into hybrid energy systems for cogeneration** were limited and therefore draws on broader nuclear cogeneration experience (e.g., desalination, district heating, process heat). This matters for plausibility and maturity because it highlights that “SMR + heat” deployment requires additional safety-case and systems-integration work beyond the reactor core. [24]

### 15) **TANDEM Deliverable D4.5: summary report on safety case studies for an SMR with cogeneration**

Organisation: TANDEM project consortium (public deliverable)

Venue/type: Euratom-funded technical report (PDF)

Publication date: **June 2025**

Link: [https://tandemproject.eu/wp-content/uploads/2025/12/D4\\_5\\_summary\\_report\\_on\\_safety\\_case\\_studies\\_for\\_a\\_smr\\_with\\_c](https://tandemproject.eu/wp-content/uploads/2025/12/D4_5_summary_report_on_safety_case_studies_for_a_smr_with_c)

ogeneration\_V1.pdf

Annotation: Summarises safety-case studies and methods for SMRs operating with cogeneration and flexibility, including evaluation of assessment tools and identification of further needs for implementation in hybrid systems. This is maturity-relevant evidence that “reactor-as-a-heat-plant” safety cases are still being formalised rather than fully standardised. [25]

#### 16) **Small Modular Reactors in Denmark: A Technology and Cost Review (Task 1 report)**

Organisation: Danish Energy Agency[26] (prepared with VTT Technical Research Centre of Finland[27] and Ea Energy Analyses[28])

Venue/type: Government-commissioned technology & cost review (PDF)

Publication date: **January 2026**

Link: <https://ens.dk/media/7783/download>

Annotation: Provides a comparative screening of SMR designs and explicitly discusses the “economy of modularity,” passive safety, licensing, fuel/waste management, and cost drivers; it also summarises design features (e.g., isolation condenser passive cooling in BWRX-300) and notes the linkage between maturity and real construction/licensing progress. This is practical maturity evidence because it combines technical design attributes with cost and regulatory readiness considerations in a national context. [29]

#### 17) **Survey on R&D Status of Japanese SMRs in OECD/NEA Activities (2022–2023) — JAEA-Review 2024-040**

Organisation: Japan Atomic Energy Agency[30]

Venue/type: National laboratory technical review report (PDF)

Publication date: **September 2024**

Link: <https://jopss.jaea.go.jp/pdfdata/JAEA-Review-2024-040.pdf>

Annotation: Discusses the SMR safety knowledge base, including how water-cooled SMRs leverage existing LWR experience while still requiring verification for novel components, and emphasises the role of **integral thermal-hydraulic test facilities** and experiments to demonstrate passive systems. This supports plausibility (physics/engineering basis) while underscoring where maturity depends on validated analysis methods and licensing acceptance. [31]

#### 18) **Fuel Fabrication Starts for MARVEL Microreactor (programme evidence for factory-built, remotely monitored nuclear units)**

Organisations: U.S. Department of Energy; Idaho National Laboratory[32]

Venue/type: Government programme update with hard milestones (official DOE article)

Publication date: **February 2024**

Link: <https://www.energy.gov/ne/articles/fuel-fabrication-starts-marvel-microreactor>

Annotation: Reports that fuel fabrication began, gives a first-fuel-shipment expectation (spring 2025), and states MARVEL is intended to evaluate **remote monitoring and autonomous control technologies** plus microgrid integration—directly relevant to the ART’s “high automation + remote support” operational claims (even though MARVEL is a microreactor rather than a 100–300 MWe SMR). This is concrete maturity evidence for the digital/operational sub-thread. [33]

**Maturity score (1–7) and reasoning**

**Final maturity score**

## 5

**Evidence-to-rubric mapping**

**Why the evidence rules out lower levels (1–4):** - Multiple SMR designs have passed **major regulator review milestones** that are far beyond lab demonstration: NRC design certification for an SMR design (final rule in early 2023) and subsequent Standard Design Approval for the uprated US460 configuration in 2025. [\[34\]](#)

- A Western regulator has issued an actual **construction licence** for an SMR project (BWRX-300 at Darlington), which indicates that the project has moved beyond proof-of-concept into regulated infrastructure execution. [\[35\]](#)

- UK regulators have completed staged generic assessments (e.g., Step 2 for BWRX-300 and Rolls-Royce SMR), supporting the interpretation that these are not speculative concepts but designs being methodically aligned to deployment requirements. [\[36\]](#)

These facts exceed rubric levels 1–4 because they demonstrate not just “working principles” or “lab prototypes,” but regulatory endorsement processes designed for **commercial nuclear construction and operation**.

**Why the score is not yet 6 (products delivered at increasing scale):** - The strongest public evidence is concentrated in **licensing approvals and early project execution authority**, not in repeated deliveries of operating SMR plants to multiple customers. A construction licence is a critical gate, but it is not the same as **multiple modules in commercial operation** with demonstrated “economy of serial production.” [\[37\]](#)

- Multiple sources still characterise deployment success as dependent on FOAK-to-NOAK learning curves, “industrialization,” and an emergent orderbook—signals of a technology that is post-PoC but not yet in broad-scale delivery mode. [\[38\]](#)

- For a substantial subset of advanced SMR variants, **fuel supply (HALEU)** remains an explicit, programme-level bottleneck, indicating that even if reactor hardware is mature, the ecosystem required for scaling is not fully in place. [\[39\]](#)

Together, this best fits **Level 5**: multiple well-capitalised actors progressing through finishing-phase design/licensing and into first builds, with significant investments and accelerating progress—but without “increasing amounts” of delivered, operating SMR products.

**Sub-component breakdown and aggregation****Light-water SMRs for grid power and cogeneration (integral PWRs, natural-circulation BWRs) → ~5**

Supporting evidence: NRC certification/SDA for NuScale; CNSC construction licence and ongoing regulator oversight for BWRX-300; UK GDA Step 2 work. [\[40\]](#)

**Advanced SMRs requiring novel fuels and/or higher enrichments (e.g., HALEU-dependent designs) → ~4–5 (closer to 4 where HALEU is mandatory)**

Supporting evidence: DOE HALEU EIS shows HALEU production is still being stood up as a strategic supply-chain effort; DOE Liftoff frames the remaining work as commercialization/industrialization and supply chain; JAEA review highlights knowledge-base gaps and verification needs for advanced technologies. [\[41\]](#)

**Industrialisation enablers: codes/standards harmonisation, QA, manufacturing readiness → ~4–5**

Supporting evidence: ARCSC documents the scale and active organisation of standards-gap closure and harmonisation work across many SDOs and stakeholders, which is necessary for repeatable module manufacturing. [23]

**Digital/remote operations thread (instrumentation, remote monitoring, autonomous control testing) → ~3–4 (demonstration-focused)**

Supporting evidence: DOE MARVEL milestone reporting indicates active testing of remote monitoring/autonomous control in a nuclear context, but the system is a microreactor test bed rather than a commercially delivered SMR fleet. [33]

**Aggregation to one score (ART as a whole):**

I use a **weighted average leaning toward the light-water SMR path**, because it best matches the ART's near- to mid-term claim of repeatable, tens-to-hundreds of MWe “packaged plants” and is the variant with the most concrete regulatory/construction evidence. The resulting overall maturity is **5**, with advanced-fuel SMRs and digital-operations elements pulling the average down from hypothetical Level 6 readiness. [42]

## ART 08.058 Thin-film solar cells

### ART extraction

- **Primary capability**
- Manufacture photovoltaic power-generating surfaces by depositing micrometre-scale semiconductor layers (“thin films”) onto substrates (glass, metal foils, flexible polymers), enabling lightweight, conformable, and potentially retrofittable “solar skins”.
- Enable new deployment form-factors (semi-transparent/colour-tunable/textured laminates; curved or nonplanar integration) rather than only maximising peak efficiency on rigid panels.
- Improve real-world output and maintainability via integration-friendly interconnects, bypassing/shading tolerance, diagnostics, and (in some variants) embedded electronics and monitoring.
- **Key sub-components / variants**
- **Commercial thin-film module families** (e.g., CdTe glass/glass utility modules).
- **Chalcopyrite thin films (CIGS/ACIGS)** for flexible laminates and BIPV-style integration (roof membranes, metal roofs, transport surfaces).
- **Organic photovoltaics (OPV)** as ultralight, flexible films (including building integration).
- **Perovskite thin films** as single-junction devices and as **thin-film-on-wafer tandems** (e.g., perovskite–silicon modules).
- **Manufacturing pathways:** roll-to-roll printing/coating, slot-die/blade coating, vapour/evaporation steps, laser scribing/interconnects.
- **Reliability package stack:** encapsulation/barrier films, edge seals, moisture/oxygen management, thermal cycling tolerance, mechanical fatigue resistance.
- **Power management elements:** interconnect architectures, bypass diodes / string reconfiguration approaches, and integration with standard inverters/DC loads.
- **Maturity indicators that would count as evidence**
- **GW-scale manufacturing & shipments**, customer deliveries, bankable warranties, and demonstrable capacity expansion financing.
- **Independent certified** cell/module efficiencies on **large areas** ( $\text{cm}^2 \rightarrow \text{m}^2$ ) and demonstrated low-lab-to-module performance loss.

- **Reliability qualification evidence:** damp-heat, thermal cycling, UV/illumination stability, mechanical bending/fatigue, and documented encapsulation/process strategies that meet mainstream PV standards.
- **Field deployments / production-format prototypes** (industrial-format panels/modules; BIPV roof systems; transport retrofits) with measurable performance.
- **Multiple well-capitalised actors / consortia activity**, including roadmaps and standardisation progress indicating credible scaling paths.

## Evidence

Evidence (10–20 recent, reliable sources)

## Annotated sources

### 1) Annual Report on Form 10-K for the fiscal year ended 31 December 2024

Authors/organisation: First Solar, Inc.[1]

Venue/type: Regulatory filing (Form 10-K; production & capacity disclosure)

Publication date: Feb 2025

Link:

[https://s202.q4cdn.com/499595574/files/doc\\_financials/2024/q4/e79628c5-f033-4b44-aae3-57b8fdd52106.pdf](https://s202.q4cdn.com/499595574/files/doc_financials/2024/q4/e79628c5-f033-4b44-aae3-57b8fdd52106.pdf)

Reports installed nameplate production capacity of ~21 GW, and that in 2024 it produced 15.5 GW and sold 14.1 GW of solar modules—strong direct evidence of large-scale thin-film (CdTe) commercial maturity and customer delivery. It also reports a 23.1% CdTe research-cell efficiency certified by National Renewable Energy Laboratory[2], signalling continued headroom in the underlying thin-film technology base. [3]

### 2) Series 7 TR1 U.S. module datasheet (505–540 W thin-film CdTe module)

Authors/organisation: First Solar, Inc.

Venue/type: Vendor technical doc (datasheet with electrical, mechanical, durability and warranty specifications)

Publication date: Jan 2023

Link: <https://www.firstsolar.com/-/media/First-Solar/Technical-Documents/Series-7/Series-7-TR1-Datasheet.ashx>

Provides product-grade metrics (e.g., 505–540 W nameplate, module efficiency up to 19.3%, temperature coefficients, glass/glass construction with edge seal) and bankability signals (30-year linear performance warranty; 0.3%/yr warranted degradation). This is concrete evidence that thin-film modules are engineered for long life and standardised deployment at scale. [4]

### 3) Cadmium Telluride Photovoltaics Perspective Paper

Authors/organisation: U.S. Department of Energy[5] (Solar Energy Technologies Office)

Venue/type: Government technical perspective / roadmap report

Publication date: Jan 2025

Link: <https://www.energy.gov/sites/default/files/2025-01/DOE%20SETO%20CdTe%20Photovoltaics%20Perspective%20Paper.pdf>

Quantifies CdTe's market position (e.g., ~34% of the United States[6] utility-scale PV market in 2022 and ~3% of global PV) and frames the scaling constraints (materials supply,

manufacturing and cost structure), directly supporting both plausibility and near-/mid-term scaling realism. [7]

#### 4) Photovoltaics Report

Authors/organisation: Fraunhofer Institute for Solar Energy Systems ISE[8]

Venue/type: Authoritative technical market/technology report

Publication date: Oct 2025 (updated)

Link:

<https://www.ise.fraunhofer.de/content/dam/ise/de/documents/publications/studies/Photovoltaics-Report.pdf>

Shows that thin-film remains commercially present but a minority share (reported as ~2–3% of global production, with ~16 GW thin-film out of ~703 GW total module production in 2024), indicating maturity for some variants but limited diffusion overall—important for judging “how close to scaling” the broader thin-film family is. [9]

#### 5) Trends in Photovoltaic Applications 2025 (IEA PVPS Task 1)

Authors/organisation: International Energy Agency Photovoltaic Power Systems Programme[10]

Venue/type: Authoritative international market/technology report

Publication date: 2025 (report year)

Link: [https://iea-pvps.org/wp-content/uploads/2025/10/IEA-PVPS\\_Trends\\_2025-.pdf](https://iea-pvps.org/wp-content/uploads/2025/10/IEA-PVPS_Trends_2025-.pdf)

Provides recent technology benchmarking: reports that crystalline silicon dominates (>98% of cell production), while thin-film module efficiencies span roughly ~14% (OPV) up to ~19.9% (CdTe) and ~19.2% (CIGS), and discusses fast progress in emerging tandems (e.g., perovskite–silicon tandem cell records cited for 2024). This contextualises thin film as both “market real” and “still niche” depending on variant and use-case. [11]

#### 6) Solar cell efficiency tables (Version 64)

Authors/organisation: Martin A. Green[12] et al.

Venue/type: Peer-reviewed benchmark compilation in Progress in Photovoltaics: Research and Applications[13]

Publication date: Jun 2024 (accepted; 2024 publication)

Link: <https://docs.nrel.gov/docs/fy24osti/90199.pdf>

Defines strict inclusion rules (independent measurement by recognised test centres, minimum areas for cells/submodules/modules) and compiles best independently confirmed efficiencies—useful for plausibility filtering (separating certified results from marketing claims) across thin-film categories and module scales. [14]

#### 7) A roadmap for tandem photovoltaics

Authors/organisation: Kirstin Alberi[15] et al.

Venue/type: Peer-reviewed review/roadmap in Joule[16]

Publication date: Mar 2024

Link: <https://docs.nrel.gov/docs/fy24osti/86496.pdf>

Synthesises what is still needed for tandems (including thin-film-on-wafer architectures like perovskite–silicon) to commercialise: measurement protocols, interconnection choices, reliability and manufacturing compatibility. This directly supports maturity assessment for the “next” thin-film wave (especially perovskite-based tandems). [17]

### 8) **High-concentration silver alloying and steep back-contact gallium grading enabling copper indium gallium selenide solar cell with 23.6% efficiency**

Authors/organisation: Jan Keller[18] et al.

Venue/type: Peer-reviewed paper in Nature Energy[19]

Publication date: Feb 2024

Link: <https://www.nature.com/articles/s41560-024-01472-3>

Reports a **23.64% certified** (Ag,Cu)(In,Ga)Se<sub>2</sub> (ACIGS) thin-film cell via Ag alloying, Ga grading and RbF post-deposition treatment—strong plausibility evidence that thin-film chalcopyrites can achieve very high performance, supporting both stand-alone and tandem roles. [20]

### 9) **Increase in the efficiency and stability of large-area flexible organic photovoltaic modules via improved electrical contact**

Authors/organisation: Xin Lu[21] et al.

Venue/type: Peer-reviewed paper (Nature Energy)

Publication date: Apr 2024

Link: <https://www.nature.com/articles/s41560-024-01501-1>

Demonstrates **certified** flexible OPV module efficiencies of **14.04%** (41 cm<sup>2</sup> active area) and **13.10%** (370 cm<sup>2</sup> active area, Voc ≈ 103.51 V) and reports retention of **~90%** of initial efficiency after **912 h** continuous illumination—direct evidence that flexible thin-film PV can scale in area while addressing stability and interconnect losses. [22]

### 10) **Large-area organic photovoltaic modules with 14.5% certified world record efficiency**

Authors/organisation: Robin Basu[23] et al.

Venue/type: Peer-reviewed report in Joule

Publication date: Apr 2024

Link: <https://www.sciencedirect.com/science/article/pii/S2542435124000990>

Achieves a **204 cm<sup>2</sup>** OPV module with **14.5% certified** efficiency on total module area (15.0% on active area) and emphasises “industry-relevant” processing (ambient air, non-halogenated solvents) with low upscaling loss—key for judging manufacturability of thin-film “skins.” [24]

### 11) **The first demonstration of entirely roll-to-roll fabricated perovskite solar cell modules under ambient room conditions**

Authors/organisation: H. C. Weerasinghe[25] et al.

Venue/type: Peer-reviewed paper in Nature Communications[26]

Publication date: Mar 2024

Link: <https://www.nature.com/articles/s41467-024-46016-1>

Reports roll-to-roll printed perovskite modules made entirely with industrial roll-to-roll tools under ambient conditions, reaching up to **15.5%** for small-area cells and **11.0%** for serially interconnected module cells; includes a cost projection of **~\$0.7/W** at **1,000,000 m<sup>2</sup>/yr** production in Australia[27]. This is direct feasibility evidence for high-throughput manufacturing. [28]

### 12) **Efficient and stable perovskite mini-module via high-quality homogeneous perovskite crystallization and improved interconnect**

Authors/organisation: Haitao Zhou[29] et al.

Venue/type: Peer-reviewed paper (Nature Communications)

Publication date: Aug 2024

Link: <https://www.nature.com/articles/s41467-024-50962-1>

Reports a **certified quasi-steady-state PCE of 22.73%** for a **14.61 cm<sup>2</sup>** perovskite mini-module and **>90%** retention after **1000 h** continuous operation under illumination—strong maturity evidence for perovskite thin films moving toward module-relevant areas with meaningful stability. [30]

### 13) Room temperature nondestructive encapsulation via self-crosslinked fluorosilicone polymer enables damp heat-stable sustainable perovskite solar cells

Authors/organisation: Tao Wang[31] et al.

Venue/type: Peer-reviewed paper (Nature Communications; via PubMed Central)

Publication date: Mar 2023

Link: <https://pmc.ncbi.nlm.nih.gov/articles/PMC10008636/>

Demonstrates room-temperature encapsulation that maintains **98%** of normalised performance after **1000 h damp heat** and **95%** after **220 thermal cycles**, explicitly framed as meeting IEC 61215 requirements; also reports very high lead-leakage suppression in water exposure tests. This directly addresses a primary thin-film (especially perovskite) bottleneck: moisture/thermal cycling and safety. [32]

### 14) Package Development for Reliability Testing of Perovskites

Authors/organisation: E. Ashley Gaulding[33] et al.

Venue/type: Peer-reviewed paper in ACS Energy Letters[34]

Publication date: Aug 2022

Link: <https://pubs.acs.org/doi/10.1021/acsenerylett.2c01168>

Presents a packaging strategy (polyisobutylene-based, low thermal budget) designed to enable outdoor and accelerated testing for perovskite devices while scaling beyond tiny lab samples—evidence of the field’s move from “cell physics” toward bankability and qualification pathways. [35]

### 15) HeliaSol® 436-2000-CFF technical datasheet

Authors/organisation: Heliatek GmbH[36]

Venue/type: Vendor technical doc (product datasheet for flexible organic solar film)

Publication date: Apr 2025 (Rev 04)

Link:

[https://www.heliatek.com/fileadmin/user\\_upload/pdf\\_documents/Datasheet\\_HeliaSol\\_436-2000\\_Website\\_EN.pdf](https://www.heliatek.com/fileadmin/user_upload/pdf_documents/Datasheet_HeliaSol_436-2000_Website_EN.pdf)

Specifies a flexible, self-adhesive thin-film solar product (claimed <2 kg/m<sup>2</sup>, ~2 mm thick solar film, minimum bending radius 50 cm) with standard-oriented specs and warranties (5-year product, 20-year performance). It is concrete evidence that “solar skins” exist as deliverable products—though at lower efficiency than mainstream modules. [37]

### 16) Flextron CIGS Solar PV Modules — Product specification

Authors/organisation: BIPVco[38]

Venue/type: Vendor technical doc (BIPV laminate module specification)

Publication date: 2024 (document filename/path indicates 2024)

Link: <https://bipvco.com/wp-content/uploads/2024/11/Flextron-CIGS-Specification-2024.pdf>

Describes flexible thin-film CIGS modules intended for factory- or site-lamination onto metal / membrane roofs, including low mass (2–3 kg/m<sup>2</sup>), “up to 17%” efficiency, integrated diodes mitigating shading losses, and 10-year material / 25-year performance warranties—evidence of near-market integrated thin-film roof systems. [39]

### 17) 55 Wp CIGS HV Solar Panel — Product Data Sheet (Transportation)

Authors/organisation: Green Energy[40]

Venue/type: Vendor technical doc (transport-oriented flexible CIGS panel datasheet)

Publication date: May 2024 (Rev 05/24)

Link: <https://greenenergy.pro/wp-content/uploads/2024/06/GE24-DataSheet-55WpHVSolarPanel.pdf>

Provides measurable “solar skin” specs: flexible CIGS panel ~3 mm thick, claimed <3.5 kg/m<sup>2</sup> installed with glue, IEC EN61730 + EN61215 stated certification, and a 25-year performance guarantee with defined retention (≥90% after 10 years; 80% after 25). This is concrete evidence of thin-film laminates targeting transport/retrofit use cases where rigid modules are impractical. [41]

### 18) Oxford PV and Fraunhofer ISE develop full-sized tandem PV module with record efficiency of 25 percent

Authors/organisation: Oxford PV + Fraunhofer ISE

Venue/type: Prototype demo (research institute press release with calibrated performance metrics)

Publication date: Jan 2024

Link: [https://www.ise.fraunhofer.de/content/dam/ise/en/documents/press-releases/2024/0424\\_ISE\\_e\\_PI\\_Oxford-PV-and-Fraunhofer-ISE-develop-full-sized-Tandem-PV-Module-with-record-efficiency-of-25-percent.pdf](https://www.ise.fraunhofer.de/content/dam/ise/en/documents/press-releases/2024/0424_ISE_e_PI_Oxford-PV-and-Fraunhofer-ISE-develop-full-sized-Tandem-PV-Module-with-record-efficiency-of-25-percent.pdf)

Reports an industrial-format glass-glass perovskite–silicon tandem module with **25%** efficiency and **421 W** output over **1.68 m<sup>2</sup>**, produced using mass-production-compatible equipment and low-temperature interconnection/encapsulation processes. This is strong “module-format” maturity evidence for thin-film perovskite layers in tandem configurations. [42]

### 19) Advances in photovoltaics — Technology trends for solar energy

Authors/organisation: European Patent Office[43]

Venue/type: Authoritative technology insight report

Publication date: Jul 2025

Link: <https://link.epo.org/web/business/technology-insight-reports/en-epo-technology-insight-report-advances-in-photovoltaics.pdf>

Provides an independent cross-technology landscape view (including perovskite and organic thin films) useful for maturity inference: it evidences broad multi-actor innovation activity beyond a single company and helps triangulate which thin-film subfamilies are drawing sustained R&D and IP investment. [44]

### Maturity score and reasoning

**Final maturity score: 6**

### Why the evidence rules out levels 1–5

Thin-film PV is not merely a lab-demonstrated principle or a single proof-of-concept: at least one thin-film branch (CdTe modules) is operating at massive commercial scale, with explicit GW-level production and sales disclosed for 2024 (15.5 GW produced; 14.1 GW sold) and substantial installed nameplate capacity (~21 GW). [45]

In parallel, there are multiple “skin-like” thin-film products available with published electrical/mechanical data and warranties (CIGS roof laminates and flexible CIGS transport

panels, plus OPV films), showing that integration as laminates/coatings is already in customer-deliverable form rather than remaining purely academic. [46]

### Why the score is not 7

Across the full ART concept (thin-film “family of coated surfaces and laminates” spanning CdTe, CIGS, OPV and perovskites), maturity is uneven. Authoritative market data indicate thin film overall remains a small fraction of global PV production (~2–3%), suggesting that, outside specific winners like CdTe utility modules, “thin-film skins everywhere” has not yet reached broad, rising mainstream demand. [47]

Moreover, the most transformative thin-film variants for novel form factors—especially perovskite modules and perovskite-based tandems—are progressing rapidly (certified ~22.7% mini-module performance and meaningful 1000 h operational stability; roll-to-roll manufacturing demonstrations), but still require longer-term bankability-grade field evidence, manufacturing yield stability, and widespread certification/insurance acceptance before qualifying as “competing products delivered and demand rising” at market-wide scale. [48]

### What evidence is still missing to justify level 7 for the ART as a whole

Level 7 would require broad competitive delivery growth across multiple thin-film “skin” product types (not only CdTe utility panels), with clear indicators that demand is rising materially in those new form-factor segments (e.g., BIPV laminates and OPV films becoming standard building products, and perovskite modules/tandems shipping in substantial volumes across multiple vendors). Current evidence shows strong prototypes and early productisation (including industrial-format tandem modules) but does not yet demonstrate market-wide scaling of the skin-like variants comparable to mainstream PV adoption. [49]

### Sub-component maturity breakdown and aggregation approach

Because the thin-film “family” spans materially different deployment modes and maturity states, the overall score is **average-weighted** (not “max”), with weight implicitly influenced by evidence of scale and deployment breadth.

- **CdTe utility-scale thin-film modules** → ~7 (mass production + large deliveries; mature datasheets/warranties). Key sources: Form 10-K production/sales at multi-GW scale and product datasheets. [50]
- **Flexible/BIPV CIGS laminates (roof + transport/retrofit)** → ~6 (deliverable products with published specs and warranties; still niche compared with mainstream PV). Key sources: Flextron specification; 55 Wp transport CIGS datasheet. [51]
- **OPV flexible films/modules** → ~5–6 (certified module efficiencies and multi-hundred-hour illumination stability in peer-reviewed work; commercial film products exist, but comparatively low efficiency and unclear scaling to large volumes). Key sources: Nature Energy OPV module paper; Joule OPV record module; HeliaSol datasheet. [52]
- **Perovskite modules and perovskite–silicon tandems** → ~4–5 (high certified mini-module performance and early manufacturing-route demonstrations; industrial-format module prototypes exist; reliability packaging work is increasingly standard-oriented, but broad market shipment/field-bankability evidence is still developing). Key sources: perovskite mini-module; roll-to-roll module paper; perovskite

encapsulation paper; industrial-format tandem module press release; tandem roadmap. [53]

### Aggregation to one score

With **one branch clearly at 7 (CdTe modules), several “skin-like” product branches around 5–6 (CIGS laminates, OPV films), and a fast-advancing but not yet broadly shipped branch around 4–5 (perovskite modules/tandems)**, the evidence supports a consolidated **ART maturity score of 6**: products exist and are being delivered (in some cases at very large scale), application areas are expanding into form-factor-driven niches, but the “full family” of thin-film skins is not yet at broad, multi-vendor, demand-rising maturity consistent with rubric level 7. [54]

[1] [15] [21] [41] <https://greenenergy.pro/wp-content/uploads/2024/06/GE24-DataSheet-55WpHVSolarPanel.pdf>

## ART 08.059 Bionic Leaf Technology

### ART extraction

#### Primary capability claimed

- A **sunlight-driven, leaf-like panel/tile** that couples **light capture and chemical conversion inside the same device**, enabling “artificial photosynthesis” rather than a separated “PV electricity → separate chemical plant” architecture.
- Direct conversion of simple inputs (water plus a carbon source such as CO<sub>2</sub> or dissolved inorganic carbon) into **storable reduced molecules** (e.g., H<sub>2</sub>, formate-like liquids, syngas, multi-carbon liquids).
- A **modular, sealed, fluid-handling form factor** with embedded sensing/control to support distributed production and remote operation.

#### Key sub-components or variants

- **Light absorbers** (e.g., silicon, perovskite, tandem stacks, photoelectrodes such as BiVO<sub>4</sub>/hematite).
- **Catalyst systems** for (i) water oxidation and (ii) CO<sub>2</sub> reduction (to CO/syngas, formate, alcohols) or alternative paired oxidation reactions (e.g., biomass/plastic oxidation to reduce required voltage).
- **Encapsulation / barrier layers** to protect moisture/ion-sensitive absorbers while permitting charge transfer and chemical contact where needed.
- **Flow-field / microchannel / reactor engineering** (gas diffusion electrodes, flow cells, modular manifolds) to manage mass transport, heat, and intermittent operation.
- **Separation and product handling** (gas separation, avoiding cross-over, liquid product collection; sometimes via paired-product strategies).
- **Scaling strategies** (cell-to-module arrays, “artificial tree”/panel assemblies, outdoor prototypes).
- **Instrumentation and control** (pressure/flow regulation, outdoor operation protocols, monitoring for degradation).

#### What maturity indicators would constitute strong evidence

- **Bias-free (unassisted) operation** with quantified solar-to-fuel / solar-to-hydrogen efficiency and verified product selectivity.
- **Large-area scaling with limited performance loss** ( $\geq 10\text{--}100\text{ cm}^2$ , progressing to  $\geq 0.1\text{--}1\text{ m}^2$  modules/arrays) plus manufacturable deposition/assembly routes.
- **Durability under realistic conditions** (hundreds to thousands of hours at relevant illumination, temperature cycling; outdoor demonstration).
- **Integrated product separation/handling** at the device/module level (especially for mixed gas products and for liquid products like formate).
- **Field trials / relevant-environment demonstrations** with logged operating data and clear degradation/maintenance pathways.

- **Evidence of industrialization push:** multiple funded consortia, pilot systems, or early customer deployments, and credible pathways for cost, safety, and maintainability.

#### **Evidence (10–20 recent, reliable sources)**

##### **1) Solar Panel Technologies for Light-to-Chemical Conversion**

- Authors/Org: Multi-author academic team (lead author V. Andrei; corresponding E. Reisner)
- Venue/type: Peer-reviewed “Account” article (thin-film solar-fuels panel classes and scale-up considerations)
- Publication date: **Dec 2022** (issue date)
- Link: <https://pmc.ncbi.nlm.nih.gov/articles/PMC9730848/>
- Why it matters: Synthesizes the “solar chemistry panel” framing (artificial leaves vs photocatalyst sheets) and explicitly foregrounds manufacturability, scale-up losses, and performance metrics needed to compare panel-like solar-to-chemical devices—directly aligning with the ART’s panel/tile premise. [1]

##### **2) The 2022 solar fuels roadmap**

- Authors/Org: Large international author team; hosted as an open report PDF (NREL document server)
- Venue/type: Authoritative roadmap (Journal of Physics D: Applied Physics “Roadmap”)
- Publication date: **Jun 2022**
- Link: <https://docs.nrel.gov/docs/fy22osti/83517.pdf>
- Why it matters: Provides consensus-like commercialization-oriented targets and bottlenecks (efficiency, stability, scale-up, cost/footprint, membranes/ions/photons management), useful for evaluating whether “bionic leaf” systems are still prototypes or approaching market readiness. [2]

##### **3) Artificial Photosynthesis Project**

- Authors/Org: **NEDO** (Japan’s New Energy and Industrial Technology Development Organization)
- Venue/type: Government program description (R&D themes include photocatalysts, separation membranes, CO<sub>2</sub>-to-chemical catalysts)
- Publication date: **Apr 2022** (“Last Updated”)
- Link: [https://www.nedo.go.jp/english/activities/activities\\_EV\\_00296.html](https://www.nedo.go.jp/english/activities/activities_EV_00296.html)
- Why it matters: Demonstrates sustained national-program investment in core enabling elements highlighted in the ART (photocatalysts, separation membranes, CO<sub>2</sub>-to-chemicals catalysis), supporting plausibility and multi-year development continuity. [3]

##### **4) Floating perovskite–BiVO<sub>4</sub> devices for scalable solar fuel production**

- Authors/Org: Multi-institution academic team
- Venue/type: Peer-reviewed experimental paper
- Publication date: **Aug 2022**
- Link: <https://www.nature.com/articles/s41586-022-04978-6>
- Why it matters: Demonstrates lightweight, flexible “artificial leaves” with reported unassisted solar-to-fuel efficiencies (H<sub>2</sub> and CO cases), scale-up to **100 cm<sup>2</sup>** devices, and **outdoor gas-collection testing**—directly addressing the ART’s modular panel and deployment concepts. [4]

##### **5) Back-illuminated photoelectrochemical flow cell for efficient CO<sub>2</sub> reduction**

- Authors/Org: Academic team (China/Singapore-linked affiliations via the paper)

- Venue/type: Peer-reviewed experimental paper (open access via PMC)
- Publication date: **Nov 2022**
- Link: <https://pmc.ncbi.nlm.nih.gov/articles/PMC9675791/>
- Why it matters: Shows **flow-cell reactor engineering** (decoupling light absorption from catalytic sites) achieving **solar-to-fuel efficiency of 2.42% for CO with ~90% Faradaic efficiency**, and high-rate operation in a flow configuration—evidence that microchannel/flow architectures can be integrated with photoelectrodes (a key “panel interior” claim). [5]

#### 6) Renewable formate from sunlight, biomass and carbon dioxide in a photoelectrochemical cell

- Authors/Org: Multi-institution academic team
- Venue/type: Peer-reviewed experimental paper
- Publication date: **Feb 2023**
- Link: <https://www.nature.com/articles/s41467-023-36726-3>
- Why it matters: Demonstrates **solar-powered formate** production using paired photoanodic biomass oxidation with photocathodic CO<sub>2</sub> reduction; reports **>85% Faradaic efficiencies** at both photoelectrodes, **32% lower cell voltage** vs conventional OER-paired designs, and a **23.3  $\mu\text{mol cm}^{-2} \text{h}^{-1}$**  formate yield—directly relevant to bionic-leaf production of transportable liquid intermediates and to separation simplification. [6]

#### 7) An artificial leaf device built with earth-abundant materials for combined H<sub>2</sub> production and storage as formate with efficiency >10%

- Authors/Org: Multi-institution European academic collaboration (paper lists institutions across Italy/Germany/Switzerland/Spain)
- Venue/type: Peer-reviewed experimental paper
- Publication date: **Feb 2023** (first published)
- Link: <https://pubs.rsc.org/en/content/articlehtml/2023/ee/d2ee03215e>
- Why it matters: Reports an integrated PV/EC “artificial-leaf-type” flow cell producing **formate + H<sub>2</sub>** with **>10% solar-to-fuel efficiency**, operating around **~17 mA cm<sup>-2</sup>**, and giving quantified formate productivity—evidence for practical device engineering using earth-abundant materials and for liquid energy carriers as “panel-edge” products. [7]

#### 8) Solar-driven liquid multi-carbon fuel production using a standalone perovskite–BiVO<sub>4</sub> artificial leaf

- Authors/Org: Academic team (UK)
- Venue/type: Peer-reviewed experimental paper
- Publication date: **May 2023** (published online)
- Link: [https://www.np.phy.cam.ac.uk/wp-content/uploads/sites/50/2024/06/natenergy23\\_bivo4leaf.pdf](https://www.np.phy.cam.ac.uk/wp-content/uploads/sites/50/2024/06/natenergy23_bivo4leaf.pdf)
- Why it matters: Demonstrates unassisted (“wireless standalone”) CO<sub>2</sub>-to-multi-carbon liquid products (ethanol/n-propanol) over an artificial leaf, albeit at early-stage rates (reported accumulation after ~20 h), which is central to plausibility for “bionic leaf → higher-value reduced liquids” beyond H<sub>2</sub>. [8]

#### 9) SUNER-C / SUNERGY Technological Roadmap (Deliverable D3.1)

- Authors/Org: SUNER-C consortium / SUNERGY initiative (Europe-wide)
- Venue/type: Consortium roadmap/report
- Publication date: **Nov 2023** (final version date shown in document history)
- Link: <https://sunergy-initiative.eu/wp-content/uploads/2024/05/D7-D3.1->

Technological-roadmap.pdf

- Why it matters: Provides an EU-centered roadmap framing for solar-to-chemicals/fuels, including timelines, TRL thinking, and ecosystem participation across academia/industry/policy—useful maturity evidence for whether bionic-leaf concepts are moving from lab novelty toward coordinated scale-up. [9]

#### 10) Natural leaf-inspired solar water splitting system

- Authors/Org: Academic team (Republic of Korea)

- Venue/type: Peer-reviewed experimental paper (Applied Catalysis B: Environmental)

- Publication date: **Mar 2023** (journal issue month)

- Link:

<https://www.sciencedirect.com/science/article/abs/pii/S092633732201027X>

- Why it matters: Implements a monolithic “leaf-inspired” architecture using crystalline-silicon interdigitated back contact (IBC) design to avoid catalyst light-blocking and reports **~8.4% solar-to-hydrogen** at the “artificial leaf” level—evidence that leaf-like geometry choices can materially affect optical/electrical integration. [10]

#### 11) Thermally integrated photoelectrochemical devices with perovskite/silicon tandem solar cells: a modular approach for scalable direct water splitting

- Authors/Org: Multi-organization European team (includes JRC Ispra outdoor testing context in-methods)

- Venue/type: Peer-reviewed experimental paper

- Publication date: **2024** (journal year; article discusses 72 h outdoor test conditions)

- Link: <https://pubs.rsc.org/en/content/articlehtml/2024/se/d4se00547c>

- Why it matters: Shows **module scaling from cell-scale to 342 cm<sup>2</sup> active area** and an **outdoor 72 h test** with quantified hydrogen volumes and STH\* efficiency computation; also documents practical control constraints (e.g., pressure/flow handling), aligning with the ART’s emphasis on thermal/fluid management and operational robustness. [11]

#### 12) A scalable integrated solar device for the autonomous production of green methane

- Authors/Org: Multi-organization European team

- Venue/type: Peer-reviewed experimental paper (system-scale demonstration; “open archive” on ScienceDirect)

- Publication date: **Aug 2024** (journal issue date)

- Link: <https://www.sciencedirect.com/science/article/pii/S254243512400240X>

- Why it matters: Reports a **TRL 5** autonomous device (**~2 m<sup>2</sup>**) combining integrated photoelectrochemical H<sub>2</sub> production with biomethanation, operating **72 h outdoors** and producing methane with a reported **~5.5% solar-to-fuel yield**—strong maturity evidence for integrated “sunlight-to-molecule” hardware operating in the field, even if the architecture is partly PV+electrolyzer. [12]

#### 13) Modular perovskite–BiVO<sub>4</sub> artificial leaves towards syngas synthesis on a m<sup>2</sup> scale

- Authors/Org: Academic team (UK)

- Venue/type: Peer-reviewed experimental paper (open access)

- Publication date: **Jan 2025** (first published; accepted Jan 2025)

- Link: <https://pubs.rsc.org/en/content/articlelanding/2025/ee/d4ee05780e>

- Why it matters: Demonstrates manufacturable scaling steps (e.g., **vacuum-processed 10 cm<sup>2</sup> PV devices** sustaining ~1 V photovoltage; **36 h** unassisted operation) and a **0.7 × 0.5 m<sup>2</sup> “artificial tree”** reactor with a 10×10 leaf array benchmarked in an **outdoor**

**demonstration**—direct evidence for modular scaling and real-world operation of leaf-like solar-fuel units. [13]

**14) Direct air capture of CO<sub>2</sub> for solar fuel production in flow**

- Authors/Org: Academic team (UK)
- Venue/type: Peer-reviewed experimental paper (open access)
- Publication date: **Feb 2025**
- Link: <https://www.nature.com/articles/s41560-025-01714-y>
- Why it matters: Addresses a key feasibility bottleneck in the ART—**carbon feed supply**—by integrating CO<sub>2</sub> capture from air with light-driven utilization in a **flow reactor** for syngas production, explicitly envisioning diurnal capture/convert operation (relevant to intermittency and system integration). [14]

**15) A standalone bismuth vanadate–silicon artificial leaf achieving 8.4% efficiency for hydrogen production**

- Authors/Org: Academic team
- Venue/type: Peer-reviewed experimental paper (open access)
- Publication date: **Mar 2025**
- Link: <https://www.nature.com/articles/s41467-025-58102-z>
- Why it matters: Reports a BiVO<sub>4</sub> photoanode stable for **>520 h** under standard illumination, a standalone artificial leaf at **8.4% STH**, and **scale-up to 441 cm<sup>2</sup>** (with performance under natural sunlight), directly supporting plausibility for larger-area, longer-lived leaf modules. [15]

**16) Scalable and durable module-sized artificial leaf with a solar-to-hydrogen efficiency over 10%**

- Authors/Org: Academic team (Republic of Korea)
- Venue/type: Peer-reviewed experimental paper (open access)
- Publication date: **May 2025**
- Link: <https://www.nature.com/articles/s41467-025-59597-2>
- Why it matters: Demonstrates a mini-module artificial leaf of **16 cm<sup>2</sup>** (4×4 array) achieving **11.2% module-level STH** in unbiased water splitting, with reported **140 h** stability for 1 cm<sup>2</sup> photoelectrodes—strong evidence that >10% efficiency can persist beyond single tiny cells and into module-style assembly. [16]

**17) Semi-artificial leaf interfacing organic semiconductors and enzymes for solar chemical synthesis**

- Authors/Org: Academic team (UK and collaborators)
- Venue/type: Peer-reviewed experimental paper (open access)
- Publication date: **Nov 2025**
- Link: <https://www.sciencedirect.com/science/article/pii/S2542435125003460>
- Why it matters: Demonstrates a biohybrid “leaf” producing **H<sub>2</sub> or formate** in bicarbonate solution with reported photocurrents (up to **–8 mA cm<sup>–2</sup>**) and **~10 h** operation, and reports a formate solar-to-fuel efficiency and Faradaic yield—evidence that “leaf-like” panels can extend beyond purely inorganic catalysts to selective liquid products, albeit still at early efficiency/durability levels. [17]

**18) (Industry milestone; use cautiously) SunHydrogen demonstrates 100 cm<sup>2</sup> and 1 m<sup>2</sup> green hydrogen panels with reported efficiency**

- Authors/Org: SunHydrogen (company communication referencing external test context)
- Venue/type: Industry announcement / technical milestone (not peer-reviewed; includes quantitative claims)
- Publication date: **Dec 2024**
- Link: <https://sunhydrogen.com/news-posts/sunhydrogen-successfully-produces-green-hydrogen-from-a-100cm2-green-hydrogen-panel-and-demonstrates-a-1m2-panel/>
- Why it matters: Indicates claims of **module-area progression** (100 cm<sup>2</sup> to 1 m<sup>2</sup>) and a reported solar-to-hydrogen efficiency number for 100 cm<sup>2</sup> modules, which—if independently validated—would be maturity-relevant evidence that “panelized” artificial-leaf concepts are being pursued beyond academia; however, this remains non-peer-reviewed and should be treated as indicative rather than definitive. [18]

### **Maturity score (1–7) and reasoning**

**Final maturity score: 4**

#### **Why the evidence rules out lower levels**

A maturity score below 4 would imply the ART is still largely at “operating principle shown” or “lab prototype only, without convincing prototype viability.” Multiple independent sources in the last four years show **functional, integrated solar-to-chemical prototypes** that go beyond single-cell benchtop demonstrations:

- **Outdoor / relevant-environment demonstrations** at multi-module scales are explicitly reported, including a **TRL 5** integrated device operating **72 h outdoors** for methane production (a full “sunlight-to-molecule” chain), and large-area integrated photoelectrochemical module work with quantified outdoor performance. [19]
- **Module/array scaling** has been demonstrated for both water splitting and CO<sub>2</sub>-to-syngas directions, including devices scaled to **hundreds of cm<sup>2</sup>** and assemblies reaching **sub-m<sup>2</sup> to m<sup>2</sup>-class reactor footprints** for outdoor benchmarking. [20]
- **Efficiency thresholds relevant to practical discussion** (often ~10% for solar-to-hydrogen) are met in at least one module-sized artificial leaf (16 cm<sup>2</sup> at >10% STH) and in a PV/EC “artificial leaf-type” formate/H<sub>2</sub> device (>10% combined solar-to-fuel), supporting the claim that key performance is not restricted to tiny proof cells. [21]

Taken together, this is best described as **Proof-of-Concept prototyping in increasingly realistic configurations**, rather than merely a verified scientific model or small lab-only prototype.

#### **What is still missing to justify the next higher level (5)**

Score 5 requires evidence that **several well-capitalized market actors** are competing to develop production prototypes post-PoC, or that a production prototype is clearly near launch with investments and manufacturing readiness.

The current evidence base still shows gaps that keep the ART below 5:

- **Durability is far from “field years”**. Even strong results are in the ~10–520 hour range or multi-day field tests, whereas roadmaps emphasize multi-year module lifetimes and scale-up stability as key commercialization barriers. [22]

- **Manufacturing and cost evidence remains limited.** While vacuum processing and modular designs are promising, there is not yet strong public evidence of repeatable, high-yield manufacturing lines, standardized balance-of-system designs, or cost curves approaching commercial solar hardware. [23]
- **Product separation / safe containment at the module edge** remains a core unresolved engineering theme—explicitly noted even in advanced “leaf” papers (e.g., gas separation challenges in module architectures) and in roadmaps focusing on membranes, scale-up, and system integration. [24]
- **Industry traction evidence is scattered and not yet dispositive:** one company announcement provides some scale claims, but it is not peer-reviewed or independently audited in the way a “products shipping” or “finishing production prototype” narrative would require. [18]

#### Sub-score breakdown (bundle assessment) and aggregation

Because “bionic leaf” is a bundle spanning multiple conversion chemistries, maturity varies by sub-thread.

- **Solar-to-hydrogen leaf-style modules → ~4**
- Rationale: Demonstrated module-sized, unbiased water splitting with >10% STH at 16 cm<sup>2</sup> and durability data into the 100+ hour range; other work shows hundreds of hours component durability and scaling into hundreds of cm<sup>2</sup>. [25]
- **Solar-to-formate / syngas (CO<sub>2</sub> reduction to C<sub>1</sub> products) in integrated/flow devices → ~4**
- Rationale: Multiple peer-reviewed demonstrations show high Faradaic efficiencies, reduced voltage via paired oxidation, flow-reactor integration, and m<sup>2</sup>-scale array demonstrations for syngas direction; still short on long-life and commodity-scale separation handling. [26]
- **Solar-to-multi-carbon liquids (e.g., ethanol/n-propanol) in standalone leaves → ~3**
- Rationale: A notable scientific milestone exists for unassisted production of multi-carbon liquids using a standalone artificial leaf, but yields/time-on-stream and robustness are still at laboratory demonstration levels. [8]
- **Integrated systems with operational control in relevant environments (pilot-like demos) → ~4**
- Rationale: Outdoor demonstrations document practical constraints (flow/pressure handling, degradation diagnosis, coupled reactor operation) consistent with PoC operation in relevant environments. [27]

**Aggregation method:** average-based across sub-components (because product targets and application paths differ materially), yielding ~3.75 → rounded to **4**. The best-evidenced sub-threads (solar-to-H<sub>2</sub> and solar-to-syngas/formate in modular reactors) reach PoC-style maturity, but the multi-carbon-liquid “bionic leaf” branch and overall commercialization readiness (durability/manufacturing/market actors) do not yet justify 5. [28]

## ART 08.060 Grid-Scale Energy Storage

### ART extraction

#### A) Primary capability (claimed by the ART)

- Provide **grid-scale, long-duration electricity storage** that can shift energy across **hours to multi-day (and potentially longer)** periods to reduce supply–demand timing mismatches.
- Operate as **infrastructure-like “storage plants”** sized independently by **power (MW)** and **energy (MWh/GWh)**, designed for durability, predictable maintenance, and siteable near existing grid infrastructure.
- Integrate **bidirectional power electronics + sensing + control software** to schedule charging/discharging against forecasts and operational constraints, while satisfying safety and permitting requirements.

#### B) Key sub-components / variants (technology bundle)

- **Electrochemical LDES:** iron–air / metal–air (low-cost, lower efficiency, multi-day); flow batteries (vanadium, all-iron and variants), other aqueous chemistries.
- **Mechanical LDES:** pumped-storage hydropower; compressed air energy storage (CAES) (incl. salt-cavern variants); other “working-fluid” stores.
- **Thermal-to-electric storage:** engineered sensible/latent heat media + power block (e.g., Stirling / Brayton / other conversion), pumped-thermal concepts.
- **Chemical carriers for longer horizons:** bidirectional hydrogen (electrolyser + storage + conversion back to power), potentially multi-week/seasonal.
- **System integration layer:** grid interconnection and reliability performance, modelling/valuation methods, digital monitoring and operational control.
- **Non-technical gating layer:** permitting, safety standards/testing, financing structures (cap-and-floor / cost-share / bankability), end-of-life and recycling.

#### C) Maturity indicators that would constitute strong evidence

Evidence that materially increases confidence in **plausibility** and **maturity** includes:

- **Grid-connected deployments** at tens to hundreds of MW (or more) and documented **discharge durations ≥10 hours**, including *multi-day* demonstrations.
- **Independent measurement & verification**, safety testing, and documented failure-mode management (thermal runaway risk, gas handling, corrosion/cycling wear).
- Authoritative **cost/performance benchmarks** (e.g., installed cost ranges, LCOS, round-trip efficiency, lifetime/cycle assumptions) and **technology roadmaps** defining concrete scaling pathways.
- Emergence of **standardised market/policy mechanisms** that make projects financeable

(e.g., cap-and-floor, public cost-share, valuation frameworks).

- Evidence of **multiple competing suppliers** and signs of early **manufacturing scale-up** (project pipelines, signed agreements, delivered plants).

## Evidence

### Evidence dossier

1) **Title:** Achieving the Promise of Low-Cost Long Duration Energy Storage

**Authors/organisation:** U.S. Department of Energy[1]

**Venue/type:** Government technical report (cross-technology synthesis; Storage Innovations 2030 / Storage Shot context)

**Publication date:** August 2024

**Link:** [https://www.energy.gov/sites/default/files/2024-](https://www.energy.gov/sites/default/files/2024-08/Achieving%20the%20Promise%20of%20Low-Cost%20Long%20Duration%20Energy%20Storage_FINAL_08052024.pdf)

[08/Achieving%20the%20Promise%20of%20Low-](https://www.energy.gov/sites/default/files/2024-08/Achieving%20the%20Promise%20of%20Low-Cost%20Long%20Duration%20Energy%20Storage_FINAL_08052024.pdf)

[Cost%20Long%20Duration%20Energy%20Storage\\_FINAL\\_08052024.pdf](https://www.energy.gov/sites/default/files/2024-08/Achieving%20the%20Promise%20of%20Low-Cost%20Long%20Duration%20Energy%20Storage_FINAL_08052024.pdf)

This report consolidates innovations and R&D “pathways” across multiple LDES classes (electrochemical, mechanical, thermal, chemical) to reduce cost toward the Storage Shot framing and explicitly treats LDES as a **portfolio** rather than a single battery. It matters as an authoritative, engineering-grounded roadmap that connects **technical levers** to **commercialisation bottlenecks** across the technology family. [2]

2) **Title:** Pathways to Commercial Liftoff: Long Duration Energy Storage

**Authors/organisation:** U.S. Department of Energy[1] (hosted copy)

**Venue/type:** Government roadmap/report (commercialisation and market adoption)

**Publication date:** March 2023

**Link:** [https://www.sandia.gov/app/uploads/sites/256/2023/09/Pathways-to-Commercial-Liftoff-LDES-May-5\\_UPDATED.pdf](https://www.sandia.gov/app/uploads/sites/256/2023/09/Pathways-to-Commercial-Liftoff-LDES-May-5_UPDATED.pdf)

The report estimates the **U.S. grid may need 225–460 GW of LDES capacity** by 2050 for a net-zero pathway (with ~\$330B cumulative capital cited) and notes the non-PSH LDES supply chain was **<1 GW deployed as of 2022**, implying urgent scale-up needs. It matters because it provides a **quantified market pull** (deployment ranges, investment magnitude) and explicitly identifies why commercial liftoff is constrained by valuation, revenue certainty, and industrialisation. [3]

3) **Title:** 2022 Grid Energy Storage Technology Cost and Performance Assessment

**Authors/organisation:** Pacific Northwest National Laboratory[4] (for DOE Energy Storage Grand Challenge)

**Venue/type:** National-lab technical report / cost & performance benchmark

**Publication date:** August 2022

**Link:**

<https://www.pnnl.gov/sites/default/files/media/file/ESGC%20Cost%20Performance%20Report%202022%20PNNL-33283.pdf>

This benchmark report compares installed cost ranges and performance assumptions across major storage technologies and explicitly expands analysis to include **24-hour and 100-hour** system durations (enabling longer-duration LCOS comparisons beyond 2–10 hours). It matters because it anchors plausibility and maturity with **cross-technology cost/performance baselines** used by policymakers, labs, and investors. [5]

4) **Title:** Technology Strategy Assessment – Flow Batteries (Findings from Storage Innovations 2030)

**Authors/organisation:** U.S. Department of Energy[1]

**Venue/type:** Government technology strategy assessment (technology roadmap)

**Publication date:** July 2023

**Link:** [https://www.energy.gov/sites/default/files/2023-](https://www.energy.gov/sites/default/files/2023-07/Technology%20Strategy%20Assessment%20-%20Flow%20Batteries.pdf)

[07/Technology%20Strategy%20Assessment%20-%20Flow%20Batteries.pdf](https://www.energy.gov/sites/default/files/2023-07/Technology%20Strategy%20Assessment%20-%20Flow%20Batteries.pdf)

This assessment sets out RD&D “flight paths” for flow batteries under the Long-Duration Storage Shot framing (10+ hour systems) and identifies where innovations must reduce cost and improve durability to reach widespread grid deployment. It matters because flow batteries are a core “power/energy decoupled” architecture aligned with the ART’s **MW vs MWh sizing** concept. [6]

5) **Title:** Technology Strategy Assessment – Thermal Energy Storage (Findings from Storage Innovations 2030)

**Authors/organisation:** U.S. Department of Energy[1]

**Venue/type:** Government technology strategy assessment (technology roadmap)

**Publication date:** July 2023

**Link:** [https://www.energy.gov/sites/default/files/2023-](https://www.energy.gov/sites/default/files/2023-07/Technology%20Strategy%20Assessment%20-%20Thermal%20Energy%20Storage.pdf)

[07/Technology%20Strategy%20Assessment%20-](https://www.energy.gov/sites/default/files/2023-07/Technology%20Strategy%20Assessment%20-%20Thermal%20Energy%20Storage.pdf)

[%20Thermal%20Energy%20Storage.pdf](https://www.energy.gov/sites/default/files/2023-07/Technology%20Strategy%20Assessment%20-%20Thermal%20Energy%20Storage.pdf)

This document frames thermal storage for long-duration electricity use, highlighting system-level integration challenges (storage medium + heat transfer + power block) and innovation pathways needed for scale and cost reduction. It matters because it captures the ART’s “storage plant” idea where **hardware durability** and **conversion efficiency** dominate economics. [7]

6) **Title:** Technology Strategy Assessment – Bidirectional Hydrogen Storage (Findings from Storage Innovations 2030)

**Authors/organisation:** U.S. Department of Energy[1]

**Venue/type:** Government technology strategy assessment (technology roadmap)

**Publication date:** July 2023

**Link:** [https://www.energy.gov/sites/default/files/2023-](https://www.energy.gov/sites/default/files/2023-07/Technology%20Strategy%20Assessment%20-%20Bidirectional%20Hydrogen%20Storage.pdf)

[07/Technology%20Strategy%20Assessment%20-](https://www.energy.gov/sites/default/files/2023-07/Technology%20Strategy%20Assessment%20-%20Bidirectional%20Hydrogen%20Storage.pdf)

[%20Bidirectional%20Hydrogen%20Storage.pdf](https://www.energy.gov/sites/default/files/2023-07/Technology%20Strategy%20Assessment%20-%20Bidirectional%20Hydrogen%20Storage.pdf)

The assessment explicitly models bidirectional hydrogen storage as a **plant** (electricity → hydrogen → electricity) and compares cost/performance pathways for storage in different configurations (e.g., tanks vs salt caverns), clarifying why duration and utilisation strongly shape economics. It matters because chemical storage is the ART’s pathway to **multi-week/seasonal** storage, despite lower round-trip efficiency. [8]

7) **Title:** Long-Duration Energy Storage Grid Integration – Valuation Framework and Incentive Gaps

**Authors/organisation:** National Renewable Energy Laboratory[9]

**Venue/type:** National-lab technical report (system integration / valuation)

**Publication date:** September 2025

**Link:** <https://www.nrel.gov/docs/fy25osti/95548.pdf>

This report focuses on how LDES value is (and is not) monetised, providing a valuation framing and identifying incentive gaps that can block deployment even when engineering

feasibility exists. It matters because “maturity” for infrastructure-like storage depends heavily on **market design, valuation methods, and compensation structures**, not only hardware readiness. [10]

8) **Title:** Economic Long-Duration Electricity Storage by Using Low-Cost Thermal Energy Storage and a High-Efficiency Power Cycle

**Authors/organisation:** National Renewable Energy Laboratory[9]

**Venue/type:** National-lab report (techno-economic analysis; ARPA-E DAYS program context)

**Publication date:** September 2023

**Link:** <https://www.nrel.gov/docs/fy23osti/87881.pdf>

This analysis evaluates a thermal-to-electric LDES architecture combining **low-cost thermal storage media** with a **high-efficiency power cycle**, directly addressing the ART’s claim that marginal cost per added hour becomes decisive for multi-day storage. It matters because it provides a quantitative-style techno-economic framing for one of the ART’s key non-battery pathways. [11]

9) **Title:** Reliability Guideline: Performance, Modeling, and Simulations of BPS-Connected Battery Energy Storage Systems and Hybrid Power Plants

**Authors/organisation:** North American Electric Reliability Corporation[12]

**Venue/type:** Grid reliability guideline (authoritative operational / modelling guidance)

**Publication date:** June 2023

**Link:**

[https://www.nerc.com/comm/PC\\_Reliability\\_Guidelines\\_DL/Reliability\\_Guideline\\_BPS\\_connected\\_BEES\\_HybridPlants.pdf](https://www.nerc.com/comm/PC_Reliability_Guidelines_DL/Reliability_Guideline_BPS_connected_BEES_HybridPlants.pdf)

This guideline targets performance requirements and modelling practices for grid-connected BESS and hybrid inverter-based plants, helping establish what “grid-ready” means beyond a lab prototype. It matters because the ART’s maturity hinges on **predictable operation** and **system-level validation** (models, simulations, interconnection behaviour). [13]

10) **Title:** Demonstrating an Aqueous Air-Breathing Energy Storage System for Multi-Day Resilience

**Authors/organisation:** California Energy Commission[14] (authors: Annie Baldwin[15] et al.)

**Venue/type:** Government project report with independent measurement & verification and safety testing

**Publication date:** November 2025

**Link:** <https://www.energy.ca.gov/sites/default/files/2025-11/CEC-500-2025-045.pdf>

The report documents kW-scale prototype module validation for an iron–air-style multi-day system, reporting **zero safety events** and **short-circuit temperature rise ~0–5°C**, and cites **~140 MW / 14 GWh** in signed agreements plus a planned **1.5 MW / 150 MWh** deployment. It matters because it provides unusually concrete, quasi-pre-commercial evidence on **safety, verification**, and early **commercial traction** for multi-day aqueous metal–air. [16]

11) **Title:** Award Wednesdays | June 5, 2024 (LDES Demonstrations Program – Multiday Iron Air Demonstration)

**Authors/organisation:** U.S. Department of Energy[1]

**Venue/type:** Government programme award notice (deployment milestone)

**Publication date:** June 2024

**Link:** <https://www.energy.gov/oced/articles/award-wednesdays-june-5-2024>

This award notice describes a plan to deploy **two 10 MW, 100-hour** iron–air LDES systems at retiring coal sites, with >\$4.3M awarded initially and up to **\$70M** federal cost-share, signalling a move from prototypes into structured, phased project delivery. It matters because publicly financed demonstration programmes are a key maturity indicator for infrastructure technologies with long permitting/build cycles. [17]

12) **Title:** Clean Energy Technology Observatory: Novel Energy Storage in the European Union – 2024 Status Report

**Authors/organisation:** European Commission Joint Research Centre[18]

**Venue/type:** Authoritative EU roadmap/status report (TRL, markets, value chains)

**Publication date:** November 2024

**Link:** [https://setis.ec.europa.eu/document/download/b24bc3ac-4f0d-43dc-abca-2dabfaf44530\\_en](https://setis.ec.europa.eu/document/download/b24bc3ac-4f0d-43dc-abca-2dabfaf44530_en)

This report surveys mechanical, electromagnetic, and thermal storage classes, including TRL positioning and market/value-chain indicators, and explicitly notes that some technologies (e.g., certain CAES variants) are closer to wide implementation while others remain developmental. It matters as a second-region, policy-relevant evidence base showing how the ART’s “family of plants” is being monitored and prioritised at continental scale. [19]

13) **Title:** Clean Energy Technology Observatory: Hydropower and Pumped Storage Hydropower in the European Union – 2024 Status Report

**Authors/organisation:** European Commission Joint Research Centre[18]

**Venue/type:** Authoritative EU status report (mature long-duration mechanical storage)

**Publication date:** November 2024

**Link:** [https://setis.ec.europa.eu/document/download/67632c8c-a010-4e74-a8c1-8659b2246707\\_en](https://setis.ec.europa.eu/document/download/67632c8c-a010-4e74-a8c1-8659b2246707_en)

The report reiterates pumped storage hydropower’s role as the dominant deployed electricity storage form (with major system-service value but site/environment constraints), illustrating the ART’s point that some options are heavily **site dependent**. It matters because it anchors the upper end of maturity for long-duration storage and highlights constraints that drive interest in more modular alternatives. [20]

14) **Title:** Long duration electricity storage consultation: Designing a policy framework to enable investment in long duration electricity storage

**Authors/organisation:** Department for Energy Security and Net Zero[21]

**Venue/type:** Government consultation (financeability / market design)

**Publication date:** January 2024

**Link:**

<https://assets.publishing.service.gov.uk/media/659bde4dd7737c000ef3351a/long-duration-electricity-storage-policy-framework-consultation.pdf>

The consultation explicitly identifies barriers consistent with the ART description—**high upfront capex, long build times**, limited technology track record (FOAK), and **insufficient revenue certainty**—and discusses a cap-and-floor style approach. It matters because policy mechanisms are a gating maturity factor for multi-day storage plants whose economics are infrastructure-like. [22]

15) **Title:** Long Duration Electricity Storage: Technical Decision Document

**Authors/organisation:** Ofgem[23] (with UK government branding)

**Venue/type:** Regulator technical decision (implementation design for cap-and-floor)

**Publication date:** March 2025 (11 March 2025)

**Link:** <https://www.ofgem.gov.uk/sites/default/files/2025-03/Long%20Duration%20Electricity%20Storage%20Technical%20Decision%20Document.pdf>

This decision document confirms key design elements of a GB LDES cap-and-floor scheme (including operational details and readiness steps), moving beyond consultation into executable rules. It matters as a high-signal maturity indicator: **finance structures are being institutionalised**, which is often prerequisite to scaling FOAK storage plants. [24]

16) **Title:** Compressed Air Energy Storage: A Case Study

**Authors/organisation:** World Bank[25] / Energy Sector Management Assistance Program[26]

**Venue/type:** Authoritative case study / knowledge note (deployment evidence + economics framing)

**Publication date:** January 2026

**Link:**

<https://documents1.worldbank.org/curated/en/099741101222620522/pdf/IDU-e56b0f51-75c8-4de7-87b1-0eef28f82012.pdf>

The note reports the Yingcheng CAES project in China[27] operating at **300 MW** with **five-hour** discharge (**1,500 MWh**) and identifies it as the largest CAES project commissioned to date and the first of its kind operating **without supplemental fuels**, using repurposed salt caverns (~700,000 m<sup>3</sup>). It matters because it is a well-sourced, third-party documentation of a **utility-scale, non-battery** long-duration plant that has crossed into operations. [28]

17) **Title:** World's Largest Flow Battery Energy Storage Station Connected to Grid

**Authors/organisation:** Chinese Academy of Sciences[29]

**Venue/type:** National research institution technical news release (grid-connection milestone)

**Publication date:** October 2024 (31 Oct 2024 implied by URL path)

**Link:**

[https://english.cas.cn/Special\\_Reports/rd/2022/202410/t20241031\\_693355.shtml](https://english.cas.cn/Special_Reports/rd/2022/202410/t20241031_693355.shtml)

This release reports the grid connection of the Dalian vanadium flow-battery peak-shaving station, with **100 MW / 400 MWh** first phase and eventual scale **200 MW / 800 MWh**, citing national demonstration status and describing operational peak-shaving use. It matters because it provides a credible, non-company confirmation of **100-MW-class flow battery deployment**, placing at least one LDES electrochemical pathway firmly beyond pilot scale. [30]

18) **Title:** China Three Gorges' 200 MW / 1,000 MWh Vanadium Flow Battery Energy Storage Project in Xinjiang Achieves Full-Capacity Operation

**Authors/organisation:** Vanitec[31] (author: Yu Li[32])

**Venue/type:** Industry association technical news / project note

**Publication date:** January 2026 (01 Jan 2026)

**Link:** <https://vanitec.org/latest-from-vanitec/article/china-three-gorges-200-mw-1000-mwh-vanadium-flow-battery-energy-storage-project-in-xinjiang-achieves-full-capacity-operation>

The note describes **200 MW / 1,000 MWh** (five-hour) VFB full-capacity operation in Xinjiang[33] paired with **1 GW PV**, reporting **RMB 3.8B** investment and operational features like intelligent thermal management and a **digital-twin O&M platform**, plus a reported ~9%

**PV utilisation uplift** and ~220 million kWh additional renewable absorption annually. It matters because it evidences scaling of flow batteries into **GWh-class projects** with explicit digital operations tooling—matching the ART’s control-software claims. [34]

19) **Title:** Experimental Demonstration of a Solar Powered High Temperature Latent Heat Storage Prototype: Preliminary Results of an Experimental Validation Campaign

**Authors/organisation:** Asem Alemam[35] et al.

**Venue/type:** Peer-reviewed conference proceedings (SolarPACES 2023 proceedings) with prototype field validation data

**Publication date:** July 2024 (Published 24 Jul 2024)

**Link:** <https://doi.org/10.52825/solarpaces.v2i.968>

The authors report a full-scale electro-thermal storage prototype monitored continuously for 10 days, maintaining near-constant electricity output of **10.5 ± 1 kW** for **13 hours** discharge, with **average cycle efficiency ~23%** and **power block efficiency ~25%**. It matters because it provides measured, real-operation evidence for thermal-to-electric storage pathways and makes clear the efficiency trade-offs that shape maturity and market fit. [36]

20) **Title:** A low-cost all-iron hybrid redox flow batteries enabled by deep eutectic solvents

**Authors/organisation:** Xusheng Cheng[37] et al.

**Venue/type:** Peer-reviewed experimental paper (Chemical Engineering Journal)

**Publication date:** July 2024 (Volume 491, 1 July 2024)

**Link:** <https://doi.org/10.1016/j.cej.2024.151936>

This paper experimentally demonstrates a deep-eutectic all-iron hybrid flow battery achieving **>98% average coulombic efficiency** over a **360-hour charge–discharge cycle** (with reported energy efficiency approaching **~54%** at 10 mA/cm<sup>2</sup> and **~100%** coulombic efficiency in early cycles). It matters because it supports the plausibility of **iron-based, low-cost** electrochemical LDES variants while also evidencing today’s efficiency limitations versus incumbent systems. [38]

### **Maturity score and reasoning**

#### **A) Final maturity score: 6**

#### **B) Why this is at least level 6 (and not lower)**

Level 4 (PoC) and below are ruled out because the dossier includes multiple examples of **operational, grid-scale plants** and structured demonstration deployments, not merely lab prototypes. The World Bank case study documents a CAES facility operating at **300 MW / 1,500 MWh** with five-hour discharge and operating without supplemental fuels, which is beyond PoC and firmly in “real asset” territory. [28]

Likewise, flow-battery technology has crossed into **100-MW-class grid-connected** operation (first phase **100 MW / 400 MWh**) with ambitions to scale higher, as reported by a national research institution, and subsequent reporting indicates **200 MW / 1,000 MWh** operation with explicit operational tooling (thermal management, digital twin O&M). [39]

#### **C) Why this is not yet level 7 (what is still missing)**

A level 7 judgement would require that *competing* long-duration products are being delivered broadly, with demand rising across many regions and competition largely internally financed (i.e., a mature, self-sustaining market across most variants). The U.S. “Commercial Liftoff” report explicitly characterises the non-pumped-hydro LDES supply chain as **nascent (<1 GW**

**deployed as of 2022)** and argues that annual manufacturing/deployment capacity must grow sharply (order-of-magnitude increases) to meet projected needs—an indicator that many LDES segments do **not yet** have fully mature, scalable supply chains. [40]

Further, policy and revenue mechanisms are still being finalised in major markets (e.g., GB moving from consultation to technical decision and scheme design), implying that “bankable scaling” remains an active workstream rather than a settled, globally standardised condition. [41]

### Subcomponent maturity breakdown

#### Sub-component → maturity estimate → key supporting source(s)

- Pumped-storage hydropower (mature long-duration mechanical storage) → **7** → EU status reporting plus cross-technology benchmarks treating PSH as established infrastructure. [42]
- Compressed air energy storage at utility scale (CAES) → **6** → Documented operational 300-MW-class plant case study and market context. [28]
- Vanadium flow batteries at utility scale (VRFB) → **6** → 100-MW-class grid connection and subsequent 200 MW / 1,000 MWh full-output operation reporting. [39]
- Iron–air / aqueous air-breathing multi-day batteries → **5** → Independent module verification + safety testing + early commercial agreements and demonstration-funded deployments, but still early in volume delivery. [43]
- Thermal-to-electric storage (power-to-heat-to-power variants) → **4** → Prototype field validation shows functionality but also low round-trip efficiency; techno-economic reports indicate active optimisation rather than mass deployment. [44]
- Bidirectional hydrogen storage for grid applications → **4** → Roadmaps and plant-level modelling exist, but widespread power-sector seasonal storage deployment remains limited relative to mature options. [45]
- Low-cost iron-based flow battery chemistry improvements (lab-scale electrolyte/system advances) → **3–4** → Recent experimental evidence demonstrates cycling and efficiency metrics but not large-scale field deployment. [38]

#### Aggregation method → single score

Because the ART is explicitly a **bundle** of storage plant types (electrochemical + mechanical + thermal + chemical) serving broadly similar system functions but at different durations and with different siting constraints, the score is based on an **average-by-commercial-weight** approach rather than a maximum. Mature incumbents (notably PSH) pull the ceiling upward, while multi-day electrochemical and thermal/chemical pathways are still moving through demonstration and early bankability stages; taken together, the evidence best fits **level 6**: multiple technologies are being delivered and operated at meaningful scale, with strong institutional financing and policy mechanisms emerging, but not yet a universally mature, self-sustaining market across all variants. [46]

---

## ART 08.061 Solid-State Batteries

### ART extraction

#### Primary capability the ART claims

- Replace today's flammable liquid electrolyte with a **solid ion-conducting electrolyte layer** to improve safety (reduced thermal-runaway/fire risk) while maintaining usable ion transport.
- Enable **higher energy density**—especially via **lithium-metal anodes** (instead of graphite) and tighter packaging—without sacrificing reliability under cycling.
- Deliver **practical, modular packs** (cells → modules → packs) whose operation is made predictable and safe via monitoring (temperature/pressure/impedance) and battery-management controls.

#### Key sub-components or variants

- **Solid electrolyte families:** sulfides (e.g., argyrodites), oxides/garnets (e.g., LLZO/LLZTO), halides (chloride/bromide systems), polymers, and hybrid “gel/solid-state” electrolytes. [1]
- **Interface engineering:** engineered interlayers/coatings, microstructure densification, and mechanically robust lamination/co-rolling to maintain intimate solid–solid contact and suppress dendrite/filament growth. [2]
- **Lithium-metal management approaches:** thin Li foils, Li-free/reservoir-free concepts, uniform plating/stripping protocols, and manufacturing routes for high-quality thin lithium films at scale. [3]
- **Cell engineering for scale:** pouch-cell architecture and “passive-mass dilution” via larger electrode areas / stack counts; robust thin electrolyte membranes; tolerable stack-pressure requirements. [4]
- **Manufacturing and QC:** dry-room/moisture handling, defect/void control, film handling, and process tolerance windows (yield, thickness uniformity, contamination control). [5]
- **System integration constraints:** pack-level thermal/pressure management, monitoring, and qualification/validation pathways (automotive-style A/B/C samples, demo vehicles). [6]

#### What maturity indicators would constitute evidence

- **Cell-level demonstrations** in relevant form factors (multi-layer pouch cells) with clearly stated **energy density, areal capacity, cycle life, and safety/abuse** behaviour. [7]
- **Evidence that key blockers are being reduced:** dendrite/short mitigation at higher current density; reduced stack-pressure dependence; stable interfaces over long cycling. [8]

- **Pilot-line / scale-up evidence:** credible manufacturing routes (dry-process films, roll-to-roll, densification) and techno-economic or process-capacity analyses tied to gigafactory-like throughput constraints. [5]
- **Customer/field validation:** shipments of prototype cells, automotive qualification steps, and (strongest) **vehicle integration trials**. [9]

Evidence (10–20 recent, reliable sources)

Peer-reviewed experimental and cell-engineering evidence

1) **A scalable and long-cycle-life 600 Wh kg<sup>-1</sup> solid-state lithium metal pouch cell**

- **Authors/org:** Xudong Peng[10] et al.
- **Venue/type:** Peer-reviewed open-access journal article.
- **Publication date:** Nov 2025.
- **Link:** [11]
- **What and why:** Reports an **~11 Ah-class** Li-metal pouch cell achieving **~604 Wh/kg** (package-included) and **>100 cycles** with **~92.83% energy retention** under **lean electrolyte** conditions—direct evidence that very high specific energy can be reached in multi-layer, pouch-format designs (though still early-life by automotive standards). [12]

2) **High plating currents without dendrites at the interface between a lithium anode and solid electrolyte**

- **Authors/org:** Dominic L. R. Melvin[13] et al.
- **Venue/type:** Peer-reviewed open-access journal article.
- **Publication date:** Sep 2025.
- **Link:** [14]
- **What and why:** Shows that densifying a sulfide solid electrolyte (Li<sub>6</sub>PS<sub>5</sub>Cl) to **~99% relative density** can raise the **critical current density** from ~1 to **~10 mA/cm<sup>2</sup>**, with **no dendritic cracks observed at 9 mA/cm<sup>2</sup>**, addressing one of the core feasibility blockers (dendrite-induced shorting) at higher plating rates. [15]

3) **Robust interface and reduced operation pressure enabled by co-rolling dry-process for stable all-solid-state batteries**

- **Authors/org:** Dong Ju Lee[16] et al.
- **Venue/type:** Peer-reviewed open-access journal article.
- **Publication date:** May 2025.
- **Link:** [17]
- **What and why:** Demonstrates a **dry-process co-rolling** approach that improves film integrity and enables long-term cycling at **much lower stack pressure** (e.g., **~2 MPa**) while sustaining **high areal capacities (~3–4 mAh/cm<sup>2</sup>)** for **~500 cycles**; this directly targets pack-level practicality because maintaining high pressure is a major system-integration penalty. [18]

4) **Advanced parametrization for the production of high-energy solid-state lithium pouch cells containing polymer electrolytes**

- **Authors/org:** Wonmi Lee[19] et al.
- **Venue/type:** Peer-reviewed open-access journal article.
- **Publication date:** Jul 2024.
- **Link:** [20]
- **What and why:** Reports practical pouch-cell builds, including an **~1 Ah** cell at **~280 Wh/kg**

and an **~0.5 Ah** cell at **~310 Wh/kg**, with explicit accounting for packaging and passive parts; also notes **third-party certification** of specific energy for a demonstrated pouch cell, strengthening credibility around “beyond-coin-cell” maturity. [21]

#### 5) A $\text{LaCl}_3$ -based lithium superionic conductor compatible with lithium metal

- **Authors/org:** Yi-Chen Yin[22] et al.
- **Venue/type:** Peer-reviewed journal article.
- **Publication date:** Apr 2023.
- **Link:** [23]
- **What and why:** Introduces a Ta-doped  $\text{LaCl}_3$ -based conductor with **~3.02 mS/cm conductivity at 30 °C** and reports **>5,000 h Li-Li symmetric cycling** ( $1 \text{ mAh/cm}^2$ ), plus **>100 cycles** in a full cell at **4.35 V cut-off** with **>1 mAh/cm<sup>2</sup> areal capacity**—strong evidence that halide SSEs can combine high conductivity with improved Li-metal compatibility. [23]

#### 6) Beneficial redox activity of halide solid electrolytes empowering high-performance anodes in all-solid-state batteries

- **Authors/org:** Zhu Cheng[24] et al.
- **Venue/type:** Peer-reviewed journal article.
- **Publication date:** Jul 2025.
- **Link:** [25]
- **What and why:** Reports “dynamic stability” in halide SSEs (e.g.,  $\text{Li}_3\text{YCl}_3\text{Br}_3$ ,  $\text{Li}_2\text{ZrCl}_6$ ), with demonstrations including **~7.65 mAh/cm<sup>2</sup> areal capacity** and **~70% retention after 1,000 cycles** for halide-based full cells, arguing that certain SSE redox activity can be reversible and performance-positive—relevant to plausibility of stable interfaces and high-loading electrodes. [26]

#### 7) Effect of pulse-current-based protocols on the lithium dendrite formation and evolution in all-solid-state batteries

- **Authors/org:** V. Reisecker[27] et al.
- **Venue/type:** Peer-reviewed open-access journal article.
- **Publication date:** Apr 2023.
- **Link:** [28]
- **What and why:** Demonstrates that a MHz pulse-current protocol can enable all-solid-state Li-metal cells operating up to **~6.5 mA/cm<sup>2</sup>**, explicitly linking protocol design to dendrite risk (stress/fracture at defects) and showing that “software/control” approaches can complement materials solutions for fast charge. [28]

#### 8) An electron-blocking interface for garnet-based quasi-solid-state lithium-metal batteries to improve lifespan

- **Authors/org:** Chang Zhang[29] et al.
- **Venue/type:** Peer-reviewed open-access journal article.
- **Publication date:** Jun 2024.
- **Link:** [30]
- **What and why:** Uses a KF-derived interlayer (forming KF/LiF) on LLZTO to reduce electron leakage and inhibit dendrites; reports Li-symmetric cycling of **~3,000 h at 0.2 mA/cm<sup>2</sup>**, and full-cell cycling to **~3,500 cycles** (72.5% retention at 2C, 25 °C), illustrating meaningful progress on garnet-interface durability. [31]

#### Manufacturing, scale-up, and cost/throughput analyses

### 9) **Scaling up high-energy-density sulfidic solid-state batteries: A lab-to-pilot perspective**

- **Authors/org:** Darren H. S. Tan[\[32\]](#) et al.
- **Venue/type:** Peer-reviewed perspective (manufacturing scale-up).
- **Publication date:** Aug 2022.
- **Link:** [\[33\]](#)
- **What and why:** Consolidates practical scale-up constraints (moisture handling, dry processing, cell assembly and the implications of stack pressure) and argues that many published ASSB results remain tied to impractical lab form factors—directly supporting the ART’s manufacturing-cleanliness/contact requirements as key maturity bottlenecks. [\[34\]](#)

### 10) **Techno-economic assessment of thin lithium metal anodes for solid-state batteries**

- **Authors/org:** Matthew Burton[\[35\]](#) et al.
- **Venue/type:** Peer-reviewed open-access analysis.
- **Publication date:** Dec 2024.
- **Link:** [\[36\]](#)
- **What and why:** Evaluates scalable routes for producing thin lithium films compatible with gigafactory volumes and identifies **thermal evaporation** as a potentially cost-effective approach; provides quantified throughput framing (e.g., area-per-year equivalents) and highlights defect/thickness control as a QC priority—directly tied to whether Li-metal-based solid-state cells can reach cost/scale. [\[36\]](#)

### 11) **A Roadmap for Solid-State Batteries**

- **Authors/org:** Thomas Schmaltz[\[37\]](#) et al.
- **Venue/type:** Peer-reviewed open-access perspective/roadmap.
- **Publication date:** Oct 2023 (first published).
- **Link:** [\[38\]](#)
- **What and why:** Synthesises materials choices, hybrid concepts, production routes, and the long qualification cycles typical in automotive deployment; it explicitly frames cost, safety, and production uncertainty as gating factors, aligning with the ART’s claims that maturity is as much a manufacturing/interfaces challenge as a materials one. [\[39\]](#)

### 12) **Development perspectives for lithium-ion battery cell formats**

- **Authors/org:** Fraunhofer ISI[\[40\]](#) (report team).
- **Venue/type:** Authoritative research institute report.
- **Publication date:** Nov 2022.
- **Link:** [\[41\]](#)
- **What and why:** Provides a structured industry-facing discussion of future cell formats and explicitly identifies **polymers, oxide-based, and sulfide-based solid electrolytes** as key classes, noting the requirement for chemical/mechanical stability against Li-metal and dendrite growth—useful as a neutral framing of design trade-offs and manufacturability. [\[42\]](#)

### 13) **A Review on Solid State Batteries: Life Cycle Perspectives**

- **Authors/org:** Ramsharan Pandey[\[43\]](#) et al., via OSTI.gov[\[44\]](#) record.
- **Venue/type:** National-lab technical report (life-cycle and manufacturing hotspot review).
- **Publication date:** Sep 2024.
- **Link:** [\[45\]](#)
- **What and why:** Summarises SSB advantages and highlights that **interface stability** is a primary commercialization barrier; from an LCA framing, it notes solid-electrolyte manufacturing as a major hotspot and that production routes can diverge from conventional

Li-ion—relevant to the ART claim that bottlenecks shift toward QC, materials supply, and recycling pathways. [45]

#### Industry scale-up signals and prototype/field evidence

##### 14) Idemitsu and Toyota Announce Beginning of Cooperation toward Mass Production of All-Solid-State Batteries for BEVs

- **Authors/org:** Toyota Motor Corporation[46] and Idemitsu Kosan Co.,Ltd.[47] (joint announcement).
- **Venue/type:** Industry programme announcement (pilot facility + launch planning).
- **Publication date:** Oct 2023.
- **Link:** [48]
- **What and why:** Describes phased work on **sulfide solid electrolytes**, preparation and construction of a **large pilot facility**, and a target to launch BEVs with all-solid-state batteries in **2027–28**—credible evidence of industrial commitment and an explicit scaling timeline, albeit not proof of volume delivery yet. [48]

##### 15) BMW Group and Solid Power are testing all-solid-state battery cells in a BMW i7

- **Authors/org:** BMW Group[49] (author: Bernhard Ederer[50]).
- **Venue/type:** OEM press release describing in-vehicle testing programme.
- **Publication date:** May 2025.
- **Link:** [51]
- **What and why:** States that large-format all-solid-state cells are integrated into a test vehicle operated in the Munich[52] area, with investigations into cell expansion management, operating pressure, and temperature control—strong maturity evidence that pack integration and vehicle-relevant validation have begun. [53]

##### 16) Q1 Fiscal 2024 Letter to Shareholders

- **Authors/org:** QuantumScape[54] (corporate letter; no individual authors listed).
- **Venue/type:** Company technical update / investor document (prototype metrics; company-tested).
- **Publication date:** Apr 2024.
- **Link:** [55]
- **What and why:** Reports prototype-sample progression (including shipment of earlier prototype cells to automotive customers at end-2022) and presents in-house test metrics such as **10–80% fast charge in <15 minutes** under specified conditions and a stated target of **>800 Wh/L** for the planned design—useful maturity evidence of iterative sample delivery, while still requiring independent validation and long-duration qualification. [56]

##### 17) ProLogium Unveils Solid-state Battery Creation Process, Plans to Start Mass Production in 2023

- **Authors/org:** ProLogium Technology[57] (press release).
- **Venue/type:** Company manufacturing/scale announcement (treat as self-reported).
- **Publication date:** Jun 2022.
- **Link:** [58]
- **What and why:** Claims roll-to-roll pilot-line operation, a planned **3 GWh** plant ramp, and self-reported manufacturing KPIs (e.g., **99.9% single-layer yield**) and shipment figures (including large-format **~50–60 Ah EV cells**)—helpful as a market-actor signal but should be treated cautiously because figures are not independently audited in the release. [59]

## Maturity score (1–7) and reasoning

### Final maturity score: 5

[60]

### Evidence-to-rubric mapping

#### Why level 5 (and not lower):

- Levels **2–3** are exceeded because multiple peer-reviewed works demonstrate not only lab principles but **integrated cell prototypes** addressing previously blocking issues (e.g., dendrite suppression at higher current density via microstructural densification, and reduced-pressure operation via co-rolled dry-process interfaces). [61]
- Level **4 (PoC)** is exceeded because the technology is being demonstrated in **commercially relevant form factors** (Ah-class pouch cells with quantified specific energy) and is beginning **system/vehicle integration work** (an OEM road test programme), which is beyond a purely scientific PoC. [62]
- Level **5** is supported by clear evidence of **multiple well-capitalised actors** executing pilot-facility plans and prototype-sample programmes, including explicit timelines to launch (2027–28 target in a major automotive programme) and iterative automotive sample shipments reported by a major developer. [63]

#### What is still missing for level 6:

- Level **6** requires convincing evidence that solid-state battery products are being **delivered to customers in increasing amounts**, with scaling that credibly implies learning-curve cost reductions and expanding applications. The strongest public evidence in this dossier is still dominated by **prototype/pilot** status: advanced pouch-cell demonstrations often remain at **hundreds of cycles (not thousands in EV-relevant conditions)**, and some require **elevated temperature and/or stack pressure**, signalling remaining pack-integration complexity. [64]
- A level-6 case would likely need: (i) sustained, independently verified automotive qualification results, (ii) production-line yields and throughput data showing consistent large-format manufacturing, and (iii) credible cost-down trajectories versus incumbent Li-ion—none of which are yet demonstrated conclusively in the open literature and documents cited here. [65]

### Sub-component maturity notes and aggregation

Because the ART description is centred on **high-energy, safer, scalable solid-state cells (often Li-metal)** and their integration into packs, the variants below are treated as a single functional family; maturity is therefore taken as the **maximum consistent level supported across the strongest evidence**, rather than averaging across unrelated niche applications.

- **Interface/dendrite suppression in inorganic SSE systems** → **~4–5** (lab-to-prototype maturity): demonstrated improvements such as **CCD ~10 mA/cm<sup>2</sup>** in densified sulfide SSE and long-cycle strategies at reduced pressure, but still with significant engineering constraints. [61]
- **Ah-class pouch-cell engineering (polymer/hybrid and all-solid variants)** → **~4–5**: repeated evidence of pouch-scale specific energy in the **~280–310 Wh/kg** class and even extreme **~600 Wh/kg** demonstrations, but cycle-life and conditions remain short of mass-market automotive requirements. [66]

- **Industrial pilot/qualification efforts** → ~5: explicit pilot-facility and automotive launch planning, plus early vehicle integration testing and reported sample shipment pipelines. [67]

**Aggregation to one score:** The overall ART maturity is set to **5** because the clearest, most recent evidence shows **post-PoC competition and pilot/qualification acceleration**, while evidence for **broad, growing customer deliveries and scaled economics** (level 6) is not yet demonstrated publicly. [68]

## ART 08.062 Green Hydrogen & Power-to-X

### ART extraction

#### A) Primary capability claimed (core “what it does”)

- Convert low-carbon electricity and water into **hydrogen**, and optionally combine hydrogen with **captured CO<sub>2</sub>** to make storable/transportable “Power-to-X” molecules (e.g., ammonia-like carriers, methanol, synthetic hydrocarbons). [1]
- Operate **flexibly and dynamically** (load-following variable renewables / price signals), rather than only at steady baseload conditions. [2]

- Run as **modular plants** (containerised up to 100-MW-class standard plant designs) with increasing use of automation, monitoring, and model-based/predictive maintenance. [3]

#### B) Key sub-components / variants (technology bundle threads)

- **Electrolysis stacks:** alkaline water electrolysis (AWE), proton exchange membrane (PEM), anion exchange membrane (AEM), and high-temperature electrolysis variants including solid oxide / proton-conducting ceramics (SOEC/PCEC). [4]
- **Balance of plant (BoP):** power electronics/rectifiers, thermal management, water purification, gas–liquid separation, compression and drying/purification. [5]
- **Power-to-X synthesis modules:** reactors to convert  $H_2 + CO_2$  (e.g., methanol) and/or  $H_2 + N_2$  (ammonia), plus conditioning, storage, and export interfaces. [6]
- **Digital control and assurance layer:** sensors, control architectures (including safety instrumented functions), monitoring/diagnostics, digital twins, and certification frameworks for “renewable hydrogen / RFNBO” claims. [7]
- **Supply-chain and materials constraints:** catalysts (notably iridium for PEM anodes), membranes/MEAs, coatings and metal components, recycling pathways, and manufacturing throughput. [8]

#### C) Maturity indicators that would count as strong evidence

- **Industrial-scale deployments** (MW-class systems) operating on realistic duty cycles (start/stop, ramping, turndown), not only lab steady-state tests. [9]
- **Market signals of scaling:** installed capacity growth, evidence of sales/manufacturing capacity expansion, standardised plant offerings, and multiple competing vendors. [10]
- **Durability and materials progress:** quantified lifetime/degradation under dynamic operation; credible pathways for scarce/critical inputs (e.g., iridium loading + recycling) and improved membranes. [11]
- **Integration progress for PtX:** pilot or demonstration coupling of electrolysis with downstream synthesis and  $CO_2$  handling, plus techno-economic studies that explicitly cover scale-up. [6]
- **Regulatory/safety/certification readiness:** operational safety guidance and enforceable “renewable hydrogen” rules (additionality + temporal/geographic correlation), enabling tradable origin claims. [12]

## 2. Evidence (10–20 recent, reliable sources)

### System-level deployment and scaling evidence

#### 1) Hydrogen production — Global Hydrogen Review 2024 (Hydrogen production page)

- **Organisation:** International Energy Agency [13] (IEA)
- **Venue/type:** authoritative annual tracking report (webpage section)
- **Publication date:** Oct 2024 (report edition)
- **Link:** <https://www.iea.org/reports/global-hydrogen-review-2024/hydrogen-production>
- **Why it matters:** Reports installed water electrolyser capacity reaching **1.4 GW by end-2023**, a possible **5 GW by end-2024**, and notes that “announced” capacity could be far

larger but only about **4%** has reached **FID or construction**—direct maturity evidence on real deployment vs. pipeline optimism. [14]

## 2) The European hydrogen market landscape (November 2024)

- **Organisation:** European Hydrogen Observatory[15]
- **Venue/type:** authoritative market/industrial landscape report (PDF)
- **Publication date:** Nov 2024
- **Link:** [https://observatory.clean-hydrogen.europa.eu/sites/default/files/2024-11/The%20European%20hydrogen%20market%20landscape\\_November%202024.pdf](https://observatory.clean-hydrogen.europa.eu/sites/default/files/2024-11/The%20European%20hydrogen%20market%20landscape_November%202024.pdf)
- **Why it matters:** Provides manufacturing/scaling signals, including **5.4 GW/year operational electrolyser manufacturing capacity** in Europe (as of May 2024), expected **8.8 GW/year by end-2024**, and **~65 MW electrolyser sales by European manufacturers in 2023**—useful for assessing “products delivered” vs. early-stage R&D. [16]

## Regulation, certification, and safety readiness

### 3) Renewable hydrogen — EU definition, additionality, temporal & geographic correlation; certification via voluntary schemes

- **Organisation:** European Commission[17]
- **Venue/type:** authoritative policy/implementation guidance page
- **Publication date:** page reflects delegated acts adopted June 2023; includes transition timing (noted on the page)
- **Link:** [https://energy.ec.europa.eu/topics/eus-energy-system/hydrogen/renewable-hydrogen\\_en](https://energy.ec.europa.eu/topics/eus-energy-system/hydrogen/renewable-hydrogen_en)
- **Why it matters:** Specifies the EU’s renewable hydrogen criteria: **additionality** (new RES capacity via PPAs), and **temporal/geographic correlation** to avoid driving fossil generation; also confirms certification relies on recognised third-party “voluntary schemes.” This directly supports plausibility of embedded traceability/certification data flows in PtX commerce. [18]

### 4) Factsheet — Commission Delegated Regulation (EU) 2023/1184 (RFNBO production rules)

- **Organisation:** European Free Trade Association[19]
- **Venue/type:** standards/legal indexing factsheet
- **Publication date:** adoption **10 Feb 2023**; Official Journal listed **20 Jun 2023**
- **Link:** <https://www.efta.int/eea-lex/32023r1184>
- **Why it matters:** Provides verifiable dates and identifiers for the key EU delegated act governing “renewable fuels of non-biological origin” (renewable hydrogen and derivatives), a prerequisite for scalable certification and trade. [20]

### 5) EHSP Guidance on Hydrogen Safety Engineering — Guidance Document

- **Organisation:** Clean Hydrogen Partnership[21] (Clean Hydrogen JU / partnership)
- **Venue/type:** authoritative safety engineering guidance (PDF)
- **Publication date:** 01 May 2023
- **Link:** <https://www.clean-hydrogen.europa.eu/system/files/2023-05/EHSP%20Guidance%20on%20Hydrogen%20Safety%20Engineering%20-%20v1-Final.pdf>
- **Why it matters:** Demonstrates maturing **siting/permitting and hazard analysis** practice (consequence modelling, prevention/mitigation, and navigation of

regulations/codes/standards), which is essential for scaling real electrolyser + storage facilities. [22]

#### Electrolyser dynamic operation and control (plausibility of load-following)

##### 6) Dynamic operation of water electrolyzers: A review for applications in photovoltaic systems integration

- **Organisation/authors:** academic authors (peer-reviewed)
- **Venue/type:** peer-reviewed review article (Renewable & Sustainable Energy Reviews)
- **Publication date:** 2023 (available online/published in 2023 on ScienceDirect page)
- **Link:** <https://www.sciencedirect.com/science/article/pii/S1364032123002642>
- **Why it matters:** Summarises dynamic behaviour of low-temperature electrolyzers and identifies limiting variables (e.g., **temperature/pressure** rather than electrical response), directly supporting feasibility of “dynamic setpoint” operation under variable renewables.

[23]

##### 7) Dynamic operation of proton exchange membrane electrolyzers — Critical review

- **Organisation/authors:** academic authors (peer-reviewed)
- **Venue/type:** peer-reviewed review article (Renewable & Sustainable Energy Reviews)
- **Publication date:** Jan 2024
- **Link:** <https://research.aalto.fi/en/publications/dynamic-operation-of-proton-exchange-membrane-electrolyzerscritic/>
- **Why it matters:** Focuses on PEM electrolysis under dynamic operation and explicitly links dynamic behaviour to **degradation, safety, efficiency, and electricity-market participation**, clarifying what must be solved for reliable commercial load-following.

[24]

##### 8) Experimental studies on dynamic performance of 250-kW alkaline electrolytic system

- **Organisation/authors:** academic + industrial-scale experimental work (peer-reviewed)
- **Venue/type:** peer-reviewed experimental paper (Journal of Power Sources)
- **Publication date:** 01 Feb 2024
- **Link:** <https://www.sciencedirect.com/science/article/abs/pii/S037877532301296X>
- **Why it matters:** Reports dynamic tests on a **250 kW industrial alkaline system**; shows start-stop response on **hourly** timescales (temperature-limited) and load-step response with behaviour from **minutes to seconds**, providing concrete evidence that MW-class-relevant alkaline systems can be characterised (and improved) for renewable-following control strategies.

[25]

#### Digitalisation, monitoring, and predictive maintenance enablers

##### 9) How to build a Digital Twin for operating PEM-Electrolyser system — A reference approach

- **Organisation/authors:** academic authors (peer-reviewed)
- **Venue/type:** peer-reviewed “vision”/methods article (Annual Reviews in Control)
- **Publication date:** 2024
- **Link:** <https://www.sciencedirect.com/science/article/abs/pii/S1367578824000129>
- **Why it matters:** Describes Digital Twin architecture for electrolyser systems, explicitly tying real-time **sensor data** to optimisation, fault detection/diagnosis, and prediction—directly aligned with the ART claim of software-updated control and predictive maintenance.

[26]

#### 10) Fault diagnosis of cells in PEM electrolyzer stack under fluctuating power source

- **Organisation/authors:** academic authors (peer-reviewed)
- **Venue/type:** peer-reviewed methods paper (International Journal of Hydrogen Energy)
- **Publication date:** 06 Jan 2025
- **Link:**  
<https://www.sciencedirect.com/science/article/abs/pii/S0360319924051152>
- **Why it matters:** Proposes and validates a diagnostic method to separate **sensor faults vs stack faults** (via interleaved voltage detection and signal processing) under fluctuating input power—evidence that monitoring/automation for safe dynamic operation is technically tractable. [27]

#### Key constraints: membranes, catalysts, and supply chain

#### 11) Durable and conductive anion exchange membranes ... for water electrolysis

- **Organisation/authors:** academic authors (peer-reviewed)
- **Venue/type:** peer-reviewed materials + single-cell performance paper (International Journal of Hydrogen Energy)
- **Publication date:** 08 Mar 2024
- **Link:**  
<https://www.sciencedirect.com/science/article/abs/pii/S0360319924001836>
- **Why it matters:** Reports an AEM with **136 mS/cm conductivity at 80 °C**, <10% conductivity loss after **>1000 h** in 1 M NaOH at 80 °C, and an AEMWE single-cell achieving **3.2 A/cm<sup>2</sup> at 2 V** and operation for **>800 h**—evidence that non-PEM membrane routes are advancing toward durability targets relevant to scale-up. [28]

#### 12) Perspectives on current and future iridium demand and iridium oxide catalysts for PEM water electrolysis

- **Organisation/authors:** academic authors (peer-reviewed; open access)
- **Venue/type:** peer-reviewed analysis + catalyst constraints paper (Catalysis Today)
- **Publication date:** 01 Aug 2023
- **Link:** <https://www.sciencedirect.com/science/article/pii/S0920586123001645>
- **Why it matters:** Quantifies PEM's key scaling bottleneck (iridium) and identifies specific technical targets (e.g., **~0.1 mgIr/cm<sup>2</sup>** MEA loading and recycling) needed to avoid iridium-limited deployment; directly supports the ART's supply-chain constraint framing and what "credible scale" requires. [29]

#### 13) Updated Manufactured Cost Analysis for Proton Exchange Membrane Water Electrolyzers

- **Organisation:** National Renewable Energy Laboratory[30] (NREL)
- **Venue/type:** national lab techno-economic manufacturing cost report (technical report)
- **Publication date:** Feb 2024
- **Link:** <https://docs.nrel.gov/docs/fy24osti/87625.pdf>
- **Why it matters:** Provides a detailed manufactured-cost model including manufacturing pathways (e.g., conventional spray coating vs higher-throughput **roll-to-roll/slot-die** approaches for catalyst-coated membranes/MEAs), directly informing maturity of electrolyser manufacturability and expected economies of scale. [31]

#### 14) Water Electrolyzers and Fuel Cells Supply Chain — Supply Chain Deep Dive Assessment

- **Organisation:** U.S. Department of Energy[32]
- **Venue/type:** government supply-chain assessment (report responding to Executive Order 14017)
- **Publication date:** 24 Feb 2022
- **Link:** <https://www.energy.gov/sites/default/files/2024-12/Fuel%2520Cells%2520%26%2520Electrolyzers%2520Supply%2520Chain%2520Report%2520-%2520Final%5B1%5D.pdf>
- **Why it matters:** Maps supply chains and vulnerabilities (materials + manufacturing) for electrolyzers and fuel cells at system level—direct evidence that scale-up constraints are being treated as national industrial-base issues, not just lab challenges. [33]

#### **Siting, water, and permitting constraints (non-optional for scale)**

##### **15) Green Hydrogen: A Briefing for Land Managers**

- **Organisation:** NREL (see prior entry; organisation not repeated here)
- **Venue/type:** national lab applied briefing (technical note)
- **Publication date:** May 2023
- **Link:** <https://docs.nrel.gov/docs/fy23osti/83885.pdf>
- **Why it matters:** Provides concrete water/land/permitting considerations, including that while stoichiometric water is **9 kg water/kg H<sub>2</sub>**, real electrolysis projects often consume **~18–24 kg water/kg H<sub>2</sub>** due to demineralisation and balance-of-plant needs—directly matching the ART’s water-access and siting constraints. [34]

#### **High-temperature electrolysis and PtX integration evidence (beyond “H<sub>2</sub> only”)**

##### **16) Next Level Solid Oxide Electrolysis — upscaling potential and techno-economic evaluation for industrial use cases**

- **Organisation:** Institute for Sustainable Process Technology[35]
- **Venue/type:** research consortium / industry-linked public report (PDF)
- **Publication date:** 2023 (public report)
- **Link:** [https://ispt.eu/media/2023-SOE-public-report\\_ISPT.pdf](https://ispt.eu/media/2023-SOE-public-report_ISPT.pdf)
- **Why it matters:** Evaluates SOEC integration into real industrial contexts (ammonia, syngas/e-fuels, CO production) and quantifies efficiency framing (e.g., indicative **~33 kWh/kg H<sub>2</sub>** for SOEC vs **~48 kWh/kg H<sub>2</sub>** for low-temperature electrolysis at stack level), plus an upscaling path toward **multi-MW modules**—direct evidence supporting PtX feasibility and what remains to be validated (dynamic performance, degradation, feedstock quality). [36]

##### **17) Intermediate Temperature Proton-Conducting Solid Oxide Electrolysis Cells with Improved Performance and Durability**

- **Organisation:** West Virginia University[37] (recipient on the report)
- **Venue/type:** DOE-funded technical report (OSTI-hosted)
- **Publication date:** 30 Apr 2023
- **Link:** <https://www.osti.gov/servlets/purl/2567526>
- **Why it matters:** Demonstrates high-current operation (reported **1.46 A/cm<sup>2</sup> at 600 °C and 1.3 V**) with **5,000-hour** operation at low degradation (reported **~1 mV/kh**), strengthening plausibility for high-temperature electrolysis variants while highlighting the gap between cell achievements and commercial system deployment. [38]

##### **18) PROMET-H2 Deliverable D6.3 — Techno-economical report including potential upscaling for PROMET-H2**

- **Organisation:** PROMET-H2 consortium[\[39\]](#)
- **Venue/type:** public–private consortium deliverable (technical report / project deliverable)
- **Publication date:** Mar 2023 (Ares reference date 25/03/2023)
- **Link:** <https://promet-h2.eu/wp-content/uploads/d63.pdf>
- **Why it matters:** Describes a pressurised **25 kW PEMWE** system intended to couple to a pilot plant producing **methanol from CO<sub>2</sub>**, and frames targeted stack cost ranges (e.g., **€500–750/kW** cited as an aspiration in the deliverable) alongside scale-up cost modelling—direct PtX integration evidence, but still at pilot/demonstration maturity. [\[40\]](#)

#### Commercial product / vendor technical documentation (measurable operating envelopes)

##### 19) MC Series Modular Plants — PEM Electrolyser Systems (specification sheet)

- **Organisation:** Nel Hydrogen[\[41\]](#)
- **Venue/type:** vendor technical doc (product specification PDF)
- **Publication date:** Oct 2025 (from file path /2025/10/ and document revision shown)
- **Link:** <https://nelhydrogen.com/wp-content/uploads/2025/10/MC-Series-Modular-Plants-PD-0600-0145-Rev-A-1.pdf>
- **Why it matters:** Provides concrete “containerised modular plant” metrics: e.g., a unit producing **984 Nm<sup>3</sup>/h**, **turndown 20–100% (automatic)**, **ramp-up <15 s** (min→full), and start-up from standby **<8 min**, supporting the ART’s claim that modular plants can dynamically follow available power. [\[42\]](#)

##### 20) Industrial-Scale Water Electrolysis for Green Hydrogen Production (scalum® + automation & monitoring)

- **Organisation:** thyssenkrupp nucera[\[43\]](#)
- **Venue/type:** vendor technical doc (brochure with operational/automation claims)
- **Publication date:** Oct 2024 (from file path /2024/10/ and document filename tag)
- **Link:** [https://www.thyssenkrupp-nucera.com/wp-content/uploads/2024/10/thyssenkrupp-nucera\\_green-hydrogen\\_brochure\\_A4\\_241029\\_RZ\\_WEB.pdf](https://www.thyssenkrupp-nucera.com/wp-content/uploads/2024/10/thyssenkrupp-nucera_green-hydrogen_brochure_A4_241029_RZ_WEB.pdf)
- **Why it matters:** Claims operational flexibility (operation down to **~10% load profiles**) and describes specific automation/safety concepts (DCS + separate SIS, automated gas measurement, single-cell monitoring, and condition monitoring for predictive maintenance), aligning with the ART’s “digital control + safety + predictive maintenance” maturity storyline. [\[44\]](#)

### 3. Maturity score (1–7) and reasoning

#### A) Final maturity score: 5

#### B) Why this score fits the rubric

##### What rules out lower levels (1–4):

- The ART is far beyond “principle only” or “lab-only” for major components: there is clearly documented **GW-scale installed electrolyser capacity** globally (1.4 GW end-2023) and continuing growth, which indicates operating deployments rather than only prototypes. [\[14\]](#)
- Commercial suppliers publish concrete, measurable operating envelopes for modular/containerised systems (e.g., turndown ranges, ramp rates, start-up times), which is consistent with genuine productisation rather than purely academic PoCs. [\[45\]](#)
- Multi-hundreds-kW experimental systems show real dynamic constraints (temperature-

limited start/stop, H<sub>2</sub>-in-O<sub>2</sub> response inertia, etc.), demonstrating that the dynamic-operation problem is being solved at industrially relevant scales and that remaining issues are engineering optimisation rather than unknown science. [25]

#### **Why it does not yet justify the next higher level (6) for the ART as a whole:**

- While electrolyzers as products are clearly commercially delivered, the ART description explicitly includes **integrated, reconfigurable Power-to-X plants** (switching outputs among H<sub>2</sub> / carriers / synthetic hydrocarbons under market signals). For this integrated “plant-as-a-system” scope, the evidence shows **pilot/demonstration and early deployment**, but also that only a small fraction of announced capacity reaches **FID or construction**—a sign that scaling to widespread repeatable builds is still constrained by economics, offtake, siting, and supply chain. [46]
- Core bottlenecks highlighted in the ART description remain active constraints in the literature and roadmaps: scarce catalyst supply (iridium), manufacturability of MEAs/stacks, and durability under dynamic duty cycles. These are being addressed with quantified targets and manufacturing process improvements, but the need for order-of-magnitude improvements and high recycling rates indicates the scale-up path is not yet “routine.” [47]
- PtX beyond “H<sub>2</sub> only” is advancing, but evidence is still weighted toward **techno-economic reports and multi-MW integration roadmaps** rather than broad, repetitive commercial roll-out. For example, the SOEC/PCEC evidence shows impressive cell durability (thousands of hours) but is not yet equivalent to high-volume delivered commercial plants. [48]

#### **Rubric match for 5:**

Score **5** best matches the observed state: multiple well-capitalised actors and consortia are advancing production prototypes and standard plant offerings, but (for the full green-hydrogen-plus-PtX integrated system functionality) the evidence still points to “post-PoC, scaling underway but not yet routine,” with materially limiting constraints (electricity price, permitting/safety, materials supply, and project bankability). [49]

#### **C) Bundle sub-score breakdown and aggregation**

Because “Green Hydrogen & Power-to-X” spans multiple sub-technologies with different commercial readiness, an average-based score is appropriate.

- **Low-temperature electrolysis systems (AWE/PEM) as modular products → 6**  
Evidence: commercial product specs and operating ranges (fast ramping, turndown), plus real market manufacturing capacity/sales indicators. [50]
- **Dynamic operation + diagnostics/digital control layer → 5**  
Evidence: peer-reviewed literature on dynamic-operation impacts and actionable diagnostic/control approaches (Digital Twin guidance; fault diagnosis under fluctuating power), plus vendor descriptions of plant automation and monitoring. [51]
- **Power-to-X integration (e.g., H<sub>2</sub> + captured CO<sub>2</sub> to methanol; multi-process integration) → 4–5**  
Evidence: consortium deliverable describing a 25 kW PEMWE system intended to be coupled to a methanol-from-CO<sub>2</sub> pilot plant and explicit scale-up cost modelling; still largely “demonstration/pilot” rather than widespread delivered plants. [52]
- **High-temperature electrolysis variants (SOEC / proton-conducting ceramics) for PtX coupling → 3–4**

Evidence: multi-MW integration roadmapping and industrial use cases, plus long-duration cell/prototype validation (5,000 h) — strong technical plausibility but earlier commercial maturity than low-temperature electrolysis. [53]

**Aggregation to one score:** averaging these sub-estimates ( $\approx 6, 5, 4.5, 3.5$ ) yields  $\sim 4.75$ , rounded to **5** to reflect strong commercialisation in electrolysis hardware but incomplete maturity for “fully integrated, reconfigurable Power-to-X plants” at scale. [54]

## ART 08.063 High-Efficiency Wind Turbines

### ART extraction

### A) Primary capability claimed (what the ART enables)

- Higher **annual energy capture per unit of installed hardware** by enlarging swept area (very large rotors/blades) while keeping structures light, fatigue-resistant, and scalable to manufacture and install.
- Improved **availability and lifetime energy yield** by shifting turbines toward **cyber-physical operation**: dense sensing + models + closed-loop control to stay near aerodynamic optimum while limiting fatigue/wear.
- Expanded siting options for high-efficiency generation via **alternative wind-harvesting architectures** (e.g., vertical-axis and airborne wind energy) that can exploit turbulent or higher-altitude winds.

### B) Key sub-components / variants (sub-threads)

- Ultra-large horizontal-axis turbines (HAWTs), especially offshore: **>100 m blades**, 12–15 MW class, large rotors, high capacity factor.
- Advanced sensing & control: **preview wind sensing (LiDAR)**, feedforward pitch/yaw, model-based control, and optimisation across changing winds.
- Condition monitoring / digital twins (cyber-physical): strain/vibration/loads inference, fatigue estimation, anomaly detection, remote updates.
- Blade materials & manufacturability: **advanced composites**, longer blades, modular/segmented blades for transport and assembly, and advanced manufacturing methods.
- Durability and performance retention in harsh climates: leading-edge erosion mitigation, coatings, repair strategies, and reliability data.
- Alternative form factors: **vertical-axis wind turbines (VAWTs)** (including floating concepts) and **airborne wind energy (AWE)** systems (kites/drones/wings with tethers and ground stations).
- Permitting/standards and operational constraints: aviation/safety (AWE), noise/wake interactions, storm survivability, offshore installation logistics.

### C) Maturity indicators that would constitute evidence

- Independent **type certification** (or equivalent) and documented **prototype → commercial** transition for large turbines.
- Evidence of **at-sea commissioning / commercial installation counts**, manufacturing ramp-up, and service contracts at scale.
- Peer-reviewed results showing **quantified performance improvements** (AEP/capacity factor, load reductions, fatigue impact, wake recovery) and validated models/field tests.
- Demonstrated pathways for **manufacturing/transport/installation** of very large blades (segmentation, novel tooling, repair approaches).
- Authoritative standards/roadmaps and funded programmes addressing **erosion**, reliability, and **certification/airspace integration** (AWE).
- For VAWT/AWE specifically: **TRL statements**, funded demonstrators, operating test sites, and credible techno-economic/system-integration studies.

### Evidence (10–20 recent, reliable sources)

#### Large-rotor turbines and scaling evidence

##### 1) Vestas Annual Report 2025

**Organisation:** Vestas Wind Systems A/S[1]

**Type:** Company annual report (audited corporate report)

**Publication date:** 5 Feb 2026 (management sign-off date in report)

**Link:** <https://mb.cision.com/Main/18886/4302973/3918542.pdf>

**What it shows / why it matters:** Reports the first commercial milestones of the V236 platform, including first power at the He Dreiht offshore wind farm[2] and **52 V236-15.0 MW turbines installed during 2025**, indicating real customer delivery and ramp-up evidence beyond PoC. [3]

## 2) Vestas Annual Report 2023

**Organisation:** Vestas Wind Systems A/S

**Type:** Company annual report (audited corporate report)

**Publication date:** Feb 2024 (auditor signature dated 7 Feb 2024)

**Link:** <https://www.vestas.com/content/dam/vestas-com/global/en/investor/reports-and-presentations/financial/2023/2023-annual-report/Annual%20Report%202023.pdf.coredownload.inline.pdf>

**What it shows / why it matters:** States that the V236-15.0 MW prototype set a **363 MWh / 24h** production record and that the platform received **DNV type certification in Nov 2023**, supporting maturity of 15 MW-class hardware entering serial production. [4]

## 3) Vestas press release: “V236-15.0 MW prototype wind turbine produces first kWh”

**Organisation:** Vestas Wind Systems A/S

**Type:** Manufacturer technical press release (prototype + measurable specs)

**Publication date:** 30 Dec 2022

**Link:** <https://www.vestas.com/en/media/company-news/2022/vestas--v236-15-0-mw-prototype-wind-turbine-produces-fi-c3691167>

**What it shows / why it matters:** Documents full prototype installation at Østerild National test centre for large wind turbines[5], including **115.5 m blades**, **>43,000 m<sup>2</sup> swept area**, “around **80 GWh/year**” energy production claim (site-dependent), and a reported **capacity factor >60% (site-dependent)**—direct evidence for plausibility and industrialisation of very long blades. [6]

## 4) GE Vernova press release: “Haliade-X 14.7 MW-220 obtains full DNV type certificate”

**Organisation:** GE Vernova[7] (press release) with DNV[8] certification referenced

**Type:** Manufacturer technical press release (certification milestone)

**Publication date:** 15 Dec 2022

**Link:** <https://www.ge.com/news/press-releases/ge-renewable-energys-haliade-x-147-mw-220-obtains-full-dnv-type>

**What it shows / why it matters:** Reports independent **full type certification** for a **14.7 MW, 220 m rotor** platform and positions it for deployment at utility-scale projects, demonstrating that very large turbine classes are certified for commercial builds. [9]

## 5) Offshore Wind Market Report: 2024 Edition

**Authors/Org:** Angel McCoy[10] et al.; National Renewable Energy Laboratory (NREL) / U.S. Department of Energy[11]

**Type:** Authoritative national-lab market + technology trends report

**Publication date:** Aug 2024

**Link:** <https://docs.nrel.gov/docs/fy24osti/90897.pdf>

**What it shows / why it matters:** Quantifies global offshore turbine upscaling: 2023 global installations had capacity-weighted-average **turbine rating 9.7 MW** and **rotor diameter**

**183.4 m**, and notes the market beginning to adopt **12–15 MW** platforms; it also outlines typical **~3-year** prototype-to-commercial project timeline for Western OEMs. [12]

#### **Sensing, control, and cyber-physical operation**

##### **6) “A digital twin solution for estimating wind turbine loads and fatigue validated by a full-scale prototype”**

**Authors/Org:** Y. Koukoura[13] et al.; National Renewable Energy Laboratory

**Type:** Peer-reviewed journal article (full-scale validation)

**Publication date:** 8 Jan 2024

**Link:** <https://www.nrel.gov/docs/fy24osti/86243.pdf>

**What it shows / why it matters:** Demonstrates a digital-twin approach (using standard turbine measurements + estimation) validated on a full-scale prototype, directly supporting the ART’s “cyber-physical platform” claim for load/fatigue-aware optimisation and condition-based operation. [14]

##### **7) “LiDAR-assisted feedforward individual pitch control of a 15 MW floating offshore wind turbine”**

**Authors/Org:** A. J. Russell[15] et al.; University of Strathclyde[16] (paper repository copy)

**Type:** Peer-reviewed journal article (control + simulation methodology)

**Publication date:** 2024 (journal volume year; accepted Dec 2023)

**Link:** <https://strathprints.strath.ac.uk/88862/7/Russell-et-al-WE-2024-LIDAR-assisted-feedforward-individual-pitch-control-of-a-15-MW-floating-offshore-wind-turbine.pdf>

**What it shows / why it matters:** Reports simulation results where LiDAR-assisted feedforward IPC yields up to **54% reductions** in variability metrics for key turbine parameters under turbulent inflow, and notes that LiDAR simulation modifications were accepted into OpenFAST releases (v3.5+), supporting feasibility and toolchain readiness for advanced control in very large machines. [17]

##### **8) “Analysis and evaluation of two reference LiDAR-assisted control designs for wind turbines”**

**Authors/Org:** Cedric D. Steinmann Perez[18] et al.; Technical University of Denmark[19]

**Type:** Peer-reviewed conference article in Journal of Physics: Conference Series (TORQUE 2024)

**Publication date:** 2024 (JPCS volume year)

**Link:**

[https://backend.orbit.dtu.dk/ws/files/363468423/Steinmann\\_Perez\\_2024\\_J.\\_Phys.\\_Conf.\\_Ser.\\_2767\\_032048.pdf](https://backend.orbit.dtu.dk/ws/files/363468423/Steinmann_Perez_2024_J._Phys._Conf._Ser._2767_032048.pdf)

**What it shows / why it matters:** Evaluates practical limitations of fixed-beam commercial LiDAR for large turbines (e.g., coherence degradation with scale) and compares control architectures (Schlipf vs Bossanyi), giving engineering-relevant constraints on how close “near-optimal” cyber-physical control can be in real hardware. [20]

#### **Blades, manufacturability, and durability**

##### **9) “CFAR – Literature review: Wind turbine blades design and manufacturing”**

**Organisation:** ORE Catapult[21] (Carbon Fibre in Wind Turbine Blade at Scale programme)

**Type:** Authoritative applied R&D literature review (blade scaling constraints)

**Publication date:** 31 Mar 2022

**Link:** <https://ore.catapult.org.uk/app/uploads/2022/03/CFAR-Blade-design-and-manufacturing-Literature-Review-Final-1.pdf>

**What it shows / why it matters:** Reviews blade scaling constraints and highlights segmented-blade manufacturing/transport as a pathway: reporting an example where segmented blade “main box” assembly could be **~4 hours**, and discussing cost trade-offs (e.g., potential blade cost reduction vs added joint manufacturing cost). [22]

#### 10) “Toward the Advanced Manufacturing of Land-Based Wind Turbine Blades: Preprint”

**Authors/Org:** Pietro Bortolotti[23] et al.; National Renewable Energy Laboratory + GE research collaborators

**Type:** National-lab conference paper (preprint; manufacturing concepts)

**Publication date:** Dec 2022

**Link:** <https://docs.nrel.gov/docs/fy23osti/84397.pdf>

**What it shows / why it matters:** Identifies blade manufacturing innovation routes (including advanced/additive manufacturing concepts and modularisation focus areas) intended to lower cost, improve throughput, and support continued rotor upsizing—key for plausibility of very large blade production at scale. [24]

#### 11) ZEBRA consortium press release: “Second recyclable wind turbine blade”

**Organisation:** IRT Jules Verne[25] (with industry consortium partners)

**Type:** Consortium technical press release (full-scale blade build)

**Publication date:** 14 Dec 2023

**Link:** <https://www.irt-jules-verne.fr/wp-content/uploads/08-irt-jules-verne-cp-zebra-ven-14122023.pdf>

**What it shows / why it matters:** Reports a **77 m** recyclable thermoplastic blade manufactured at industrial blade-plant scale and describes use of advanced resin/adhesive concepts (including recycled resin use), supporting the manufacturability and circularity sub-claims for scaling high-performance blades. [26]

#### 12) “Aerodynamic effects of leading-edge erosion in wind farm flow modeling”

**Authors/Org:** Visbech et al. (DTU Wind)

**Type:** Peer-reviewed journal article (Wind Energy Science)

**Publication date:** 10 Sep 2024

**Link:** <https://wes.copernicus.org/articles/9/1811/2024/>

**What it shows / why it matters:** Provides quantified AEP impact of leading-edge erosion (LEE) via coupled erosion–aero–farm modelling (Horns Rev 1 case), reporting up to **2.9% annual AEP loss** for a turbine late in life and demonstrating that wake interactions can change farm-level loss estimates—directly relevant to maintaining “high efficiency” over operating life. [27]

#### 13) IEA Wind TCP Task 46: Erosion final report

**Organisation:** International Energy Agency[28] Wind TCP Task 46

**Type:** Authoritative international task final report (R&D synthesis / roadmap)

**Publication date:** 13 Mar 2025

**Link:** [https://eudp.dk/files/media/document/Slutrapport%20IEA-Task46-Erosion\\_1\\_13032025\\_0944.pdf](https://eudp.dk/files/media/document/Slutrapport%20IEA-Task46-Erosion_1_13032025_0944.pdf)

**What it shows / why it matters:** Frames blade leading-edge erosion as a multidisciplinary reliability and performance bottleneck and consolidates mitigation/testing directions—

evidence that durability constraints are actively being standardised and engineered (a maturity marker for long-life high-output turbines). [29]

#### **Alternative form factors: VAWT and airborne wind**

##### **14) “Large-eddy simulations of turbulent flows in arrays of helical- and straight-bladed vertical-axis wind turbines”**

**Authors/Org:** Masoumeh Gharaati[30] et al.

**Type:** Peer-reviewed journal article (Journal of Renewable and Sustainable Energy); indexed via OSTI

**Publication date:** 13 Dec 2023

**Link:** <https://www.osti.gov/pages/biblio/2282549>

**What it shows / why it matters:** Uses LES to compare array performance and reports mean power production improvements of **~4.94%–7.33%** for helical-bladed VAWTs versus straight-bladed cases in fully developed array regions, plus **~47.6%–60.1%** reduction in temporal power fluctuations—direct evidence for “turbulence-tolerant / different packing” plausibility. [31]

##### **15) “Effect of background turbulence on the wakes of horizontal-axis and vertical-axis wind turbines”**

**Authors/Org:** van der Deijl et al.

**Type:** Peer-reviewed journal article (Journal of Wind Engineering & Industrial Aerodynamics; wind-tunnel study)

**Publication date:** 2024 (month not shown on abstract page)

**Link:**

<https://www.sciencedirect.com/science/article/abs/pii/S016761052400240X>

**What it shows / why it matters:** Wind-tunnel experiments show VAWT wakes recover faster than HAWT wakes under **low-turbulence inflow**, but under moderately turbulent inflow the wake shapes become similar—important realism for claims that VAWTs can improve site packing/energy density in specific turbulence regimes. [32]

##### **16) EU CORDIS project fact sheet: VERTI-GO (floating vertical-axis offshore demonstrator)**

**Organisation:** European Commission[33] (CORDIS/Horizon)

**Type:** Authoritative programme record (Horizon Europe innovation action)

**Publication date:** EC signature date 29 Aug 2025 (project start 1 Oct 2025)

**Link:** <https://cordis.europa.eu/project/id/101235735>

**What it shows / why it matters:** States the project has already reached **TRL5 with a 30 kW demonstrator** and aims to scale to a **2 MW floating VAWT demonstrator** tested in real conditions for ~15 months, with ~€15M EU contribution—clear “field-demo funding + scaling plan” maturity evidence for floating VAWT variants. [34]

##### **17) “System design and scaling trends in airborne wind energy demonstrated for a ground-generation concept”**

**Authors/Org:** Rishikesh Joshi[35] et al.

**Type:** Peer-reviewed journal article (Wind Energy Science)

**Publication date:** 14 Apr 2025

**Link:** <https://wes.copernicus.org/articles/10/695/2025/>

**What it shows / why it matters:** Develops an integrated MDAO framework for AWE system

sizing and reports that LCoE-driven optima fall in roughly **100–1000 kW** rated power under model assumptions, identifying key cost drivers (e.g., kite mass, storage, tether replacement)—evidence for engineering plausibility and scaling constraints. [36]

#### 18) “Standardisation and Certification of Airborne Wind Energy”

**Organisation:** ORE Catapult

**Type:** Applied standards/certification report

**Publication date:** 23 Oct 2024

**Link:** <https://airbornewindeurope.org/wp-content/uploads/2024/10/Standardisation-and-Certification-of-Wind-Energy.pdf>

**What it shows / why it matters:** Lays out pathways and gaps for AWE certification and standards, including mapping against the IEC 61400 ecosystem—evidence of maturing “market infrastructure” (certification/permitting) needed before broad deployment. [37]

#### 19) RWE press release: “RWE and Kitepower deliver new test site for Airborne Wind in Ireland”

**Organisation:** RWE[38] with Kitepower[39]

**Type:** Field-trial announcement (industry test infrastructure)

**Publication date:** 25 Sep 2023

**Link:** <https://ie.rwe.com/press-and-news/2023-09-25-rwe-and-kitepower-deliver-new-test-site-for-airborne-wind-in-ireland/>

**What it shows / why it matters:** Documents an operational AWE test facility enabling maiden flight/testing at Bangor Erris (County Mayo), supporting the claim that airborne systems are moving beyond lab-only work into continuous test operations tied to industrial players. [40]

#### Maturity score (1–7) and reasoning

##### Final maturity score

6

##### Evidence-to-rubric mapping

##### What rules out lower levels (≤4):

- The dossier includes multiple examples of **independently type-certified, very large (14–15 MW class) turbine platforms** (e.g., GE Haliade-X and V236 certification references), and evidence of **commercial installation and commissioning** (e.g., dozens of V236 units installed in 2025 with first at-sea commissioning). This goes well beyond lab prototypes and PoCs. [41]
- National-lab reporting shows the offshore sector has already begun adopting **12–15 MW platform classes**, with quantified increases in capacity-weighted turbine rating and rotor diameter in recent global installations—evidence that upscaling is not only plausible but actively entering the market. [42]

##### Why this is at level 6 (not merely level 5):

- Level 6 requires **products delivered to customers in increasing amounts** and clear production expansion. The V236 platform shows installation ramp-up (installed turbine counts), and corporate reporting indicates ongoing production launch and operational scaling—matching the “delivered and increasing amounts / expansion financed” pattern. [3]

- Complementary engineering maturity is visible in adjacent enabling technologies: validated digital-twin load/fatigue estimation on a full-scale prototype and peer-reviewed demonstrations of LiDAR-assisted control benefits for very large turbine models and toolchains. [\[43\]](#)

#### **What is still missing to justify level 7 for the ART as a whole:**

- Several “alternative form factors” included in the ART description remain **pre-commercial** even if technically plausible: floating VAWT is moving through funded demonstrators (e.g., 2 MW planned, TRL5 claim from prior 30 kW) rather than broad commercial delivery. [\[44\]](#)
- Airborne wind energy has strong modelling and emerging standards work, plus test sites, but lacks evidence in this window of **multi-customer product delivery at scale** comparable to conventional turbines (i.e., deployments with broad, recurring customer demand and multiple competing shipped products). [\[45\]](#)
- Blade durability constraints (e.g., leading-edge erosion) have quantified impacts and active task-level roadmapping, but the dossier evidence emphasises continuing mitigation work rather than a fully “solved” reliability envelope for all high-tip-speed, long-life operations across regions. [\[46\]](#)

#### **Sub-component breakdown and aggregation**

Because the ART bundles **(i) mainstream ultra-large HAWTs** with **(ii) materially different architectures (VAWT, AWE)** that serve partly different sites/regulatory regimes, an average-style aggregation is more appropriate than taking the maximum.

- **Ultra-large offshore HAWTs (12–15 MW class, >100 m blades): 7** — Commercially delivered platforms with type certification and increasing installations. Key sources: Vestas Annual Report 2025; Vestas prototype/metrics release; NREL Offshore Wind Market Report 2024. [\[47\]](#)
- **Cyber-physical sensing/control & digital operation: 5–6** — Validated digital twin on a full-scale prototype and quantified load/variability reductions from LiDAR-assisted control in peer-reviewed studies, but broad “near-optimal” adaptive control as standard practice across fleets is still uneven. Key sources: NREL digital twin; Russell et al.; Steinmann Perez et al. [\[43\]](#)
- **Manufacturability innovations (segmented/advanced manufacturing, recyclable composite blades): 4–5** — Concrete prototypes and industrial-scale blade builds exist (e.g., 77 m recyclable blade), and segmentation is documented as feasible, but these approaches are not yet evidenced here as dominant, standardised mass production paths for all >100 m blades globally. Key sources: ORE Catapult CFAR review; NREL manufacturing preprint; ZEBRA press release. [\[48\]](#)
- **Durability/performance retention (erosion, repair optimisation): 6** — Measured farm-level AEP impacts, plus IEA task roadmapping and mitigation work indicate mature recognition and industrial response, though still a live bottleneck area. Key sources: Visbech et al. 2024; IEA Wind Task 46 final report. [\[46\]](#)
- **Floating VAWT: 5** — EU-funded 2 MW demonstrator programme (with stated TRL5 predecessor) indicates late-stage prototype-to-demo maturity, but not broad product delivery. Key source: EU CORDIS VERTI-GO. [\[44\]](#)
- **Airborne wind energy (AWE): 4** — Demonstrated modelling frameworks, emerging certification work, and operational test sites show functional prototypes and growing

ecosystem readiness, but not scaled product delivery. Key sources: Joshi et al. 2025; ORE AWE certification report; RWE/Kitepower test site announcement. [45]

**Aggregation to one score:** Taking a simple midpoint of the above (weighted toward the already-commercial mainstream HAWT pathway because it dominates near-term market impact and installation volume) yields an overall **6**: delivered systems scaling now, with clear remaining gaps centred on the alternative architectures and some next-generation blade/material approaches. [49]

## ART 08.064 Wireless & Space-Based Power Transfer

### 1. ART extraction

**A) Primary capability (what the ART claims)** - Deliver *usable electrical power* without cables by converting electricity into a steerable electromagnetic beam (microwave or laser) and converting it back to electricity at a receiver. [1]

- Extend that capability to *space-based solar power* (SBSP): collect solar energy in orbit (often GEO), convert to RF/optical beams, transmit to Earth receiving sites as a quasi-dispatchable generation asset. [2]

- Evolve into modular networks of transmitter nodes (ground/airborne/orbital) and receiver arrays (small mobile receivers → large rectenna fields) with closed-loop beam control and monitoring interfaces. [3]

**B) Key sub-components / variants (technology bundle)** - SBSP system architecture: orbital collectors, on-orbit DC→RF (or DC→laser) conversion, beamforming/transmission, and ground rectenna + grid interconnection. [4]

- Microwave power transmission (MPT): phased-array beamforming, beam steering, retrodirective / pilot-signal tracking, and RF→DC rectenna arrays. [5]

- Optical/laser wireless power transmission (OWPT): high-power lasers, beam shaping/homogenisation, atmospheric-turbulence tolerance, and PV (or hybrid) receivers. [6]

- Receiver and conversion hardware: high-power rectennas (RF→DC), laser PV receivers (photoelectric conversion), plus thermal management (e.g., PV-TEG hybrids). [7]

- Control, safety, and verification: pointing accuracy, beam-locked operation, misalignment safety logic, and standards/regulatory compliance (spectrum, orbital slots, safety). [8]

- Scaling enablers: mass manufacturing, launch cadence, in-space assembly/manufacturing (ISAM), and cost-reduction pathways. [9]

### **C) Maturity indicators that would constitute strong evidence - End-to-end**

**demonstrations:** beam → receiver → delivered electric power into a real load, at materially relevant ranges (km) and powers (100s W → kW), with quantified efficiency and safety procedures. [10]

- **In-space demonstrations:** power beaming performed on-orbit (even at low power), and/or space-to-ground detection that validates pointing/control and link budget in realistic conditions. [11]

- **Receiver performance:** reproducible RF→DC efficiencies and/or laser photoelectric conversion efficiencies, plus evidence of thermal stability under sustained exposure. [7]

- **Credible scaling pathways:** authoritative pre-Phase A / roadmap documents with quantified system sizing (rectenna fields, mass, launch cadence) and explicit blockers. [12]

- **Multiple well-resourced actors:** government programmes and major industrial labs conducting repeatable trials (and publishing technical details), suggesting sustained development rather than one-off stunts. [13]

### 2. Evidence (10–20 recent, reliable sources)

#### 1) Space-Based Solar Power (OTPS report)

- **Authors/Org:** NASA[14] Office of Technology, Policy, and Strategy (OTPS)

- **Venue/type:** Authoritative government report

- **Publication date:** Jan 2024 (11 Jan 2024)
- **Link:** <https://www.nasa.gov/wp-content/uploads/2024/01/otps-sbsp-report-final-tagged-approved-1-8-24-tagged-v2.pdf>
- **Why it matters:** Quantifies an end-to-end SBSP efficiency chain (e.g., DC→RF ~0.7, rectenna reception ~0.78) and estimates delivered power (~2 GW) while highlighting blockers including spectrum allocation, orbital-slot competition, debris and security/safety of power beaming—directly addressing plausibility and maturity constraints. [15]

## 2) Potential Activities for the Space Based Solar Power Specific Area in GSTP Element 1

- **Authors/Org:** European Space Agency[16] (ESA), GSTP documentation
- **Venue/type:** Government programme planning / technology roadmap document
- **Publication date:** Dec 2022 (19 Dec 2022)
- **Link:**  
<https://indico.esa.int/event/453/attachments/5098/8056/Potential%20Activities%20for%20the%20Space-based%20Solar%20Power%20Specific%20Area%20in%20GSTP%20Element%201%2022Dec22.pdf>
- **Why it matters:** Explicitly states that SBSP WPT needs substantially higher DC→RF efficiencies (targeting >70%) and describes the scale problem (phasing thousands of antennas across km-scale arrays) plus a proposed path via an MW-scale in-orbit demonstrator (with >30 m deployable antenna) by ~2030—strong maturity-signalling roadmap detail. [17]

## 3) Request for Information: Research Activities in support of Space-Based Solar Power for terrestrial needs

- **Authors/Org:** ESA SOLARIS team (ESA)
- **Venue/type:** Government RFI / research-plan scoping document
- **Publication date:** Feb 2023 (26 Feb 2023)
- **Link:**  
<https://indico.esa.int/event/453/attachments/5098/8054/Request%20for%20Information%20-%20Research%20Activities%20for%20Space-Based%20Solar%20Power.pdf>
- **Why it matters:** Shows an active, time-bounded institutional decision process (aiming to inform a 2025 decision including a first in-orbit demonstrator) and centres research uncertainties around RF power beaming in Earth's environment—evidence of “programme maturity” but also that key feasibility questions remain open. [18]

## 4) SBSP Pre-Phase A System Study – Final Report

- **Authors/Org:** Thales Alenia Space[19] (under ESA contract)
- **Venue/type:** Authoritative industrial pre-Phase A system study report (agency-contracted)
- **Publication date:** Dec 2023 (20 Dec 2023)
- **Link:**  
[https://nebula.esa.int/sites/default/files/neb\\_study/3136/FR\\_Final%20Report\\_v4\\_E-Sgn.pdf](https://nebula.esa.int/sites/default/files/neb_study/3136/FR_Final%20Report_v4_E-Sgn.pdf)
- **Why it matters:** Provides quantified commercial-scale system assumptions (e.g., 1 GW grid-power baseline; ground receiver field ~34 km<sup>2</sup> and ~70,000-ton receiver mass estimate; misalignment/safety-logic simulation) that indicate SBSP is still at “architecture and sizing” maturity rather than product maturity. [20]

### 5) Study on Cost-Benefit Analysis of Space-Based Solar Power (SBSP) Generation for Terrestrial Energy Needs – Final Report

- **Authors/Org:** Frazer-Nash Consultancy[21] (in partnership with London Economics[22])
- **Venue/type:** ESA-commissioned cost/tech feasibility report (system breakdown + economics)
- **Publication date:** Jul 2022
- **Link:** <https://www.fnc.co.uk/media/fi4pvbgv/space-based-solar-power-final-report.pdf>
- **Why it matters:** Puts concrete scale/cost numbers behind SBSP (e.g., 1.44 GW FOAK scenario; Capex and Opex ranges; LCOE range; total spacelift mass ~2,491 tonnes for one system), making clear that launch mass/cadence and industrialisation dominate readiness and time-to-market. [23]

### 6) The Caltech Space Solar Power Project: Design, Progress, and Future Direction

- **Authors/Org:** A. Fikes et al.; California Institute of Technology[24]
- **Venue/type:** Peer-reviewed conference paper (IEEE EuCAP)
- **Publication date:** Mar 2022
- **Link:** [https://www.researchgate.net/publication/364304401\\_The\\_Caltech\\_Space\\_Solar\\_Power\\_Project\\_Design\\_Progress\\_and\\_Future\\_Direction](https://www.researchgate.net/publication/364304401_The_Caltech_Space_Solar_Power_Project_Design_Progress_and_Future_Direction)
- **Why it matters:** Describes a modular “sandwich” SBSP architecture using lightweight IC-driven phased-array RF transmission and flexible PV/structure packaging (e.g., discussing nominally ~60 m × 60 m deployed structures and module scaling), supporting plausibility of modular kilometre-scale concepts while implicitly signalling early-stage maturity. [25]

### 7) The Caltech Space Solar Power Demonstration One Mission

- **Authors/Org:** A. Fikes et al.
- **Venue/type:** IEEE-style technical paper describing a space demo payload (technical documentation with mission engineering detail)
- **Publication date:** 2022 (paper text references Nov 2022 launch schedule; month-of-publication not stated in document)
- **Link:** <https://www.its.caltech.edu/~sslabor/PUBLICATIONS/2022%20IEEE%20Paper%20%231570826333.pdf>
- **Why it matters:** Specifies a multi-experiment in-space demonstrator (SSPD-1) including a microwave WPT experiment (MAPLE) and a deployable-structure experiment (DOLCE at ~1.7 m × 1.7 m scale), providing concrete prototype scope and integration approach consistent with TRL-advancing space tests. [26]

### 8) Wireless power transfer in space using flexible, lightweight, coherent arrays

- **Authors/Org:** Ayling et al.
- **Venue/type:** Peer-reviewed research paper (Acta Astronautica)
- **Publication date:** Nov 2024 (Volume 224)
- **Link:** <https://www.sciencedirect.com/science/article/abs/pii/S009457652400434X>
- **Why it matters:** Reports (to the authors’ knowledge) the first documented WPT demonstration in space using lightweight flexible phased arrays driven by custom RFICs, operated/tested over months in LEO and including pointing the beam toward Earth and

ground detection—strong plausibility evidence for orbital transmitter modules but still at small experimental scale. [27]

#### 9) First In-Space Laser Power Beaming Experiment Surpasses 100 Days of Successful On-Orbit Operations

- **Authors/Org:** U.S. Naval Research Laboratory[28]
- **Venue/type:** Government lab experiment report (official lab news release with technical metrics)
- **Publication date:** Jul 2023 (13 Jul 2023)
- **Link:** <https://www.nrl.navy.mil/Media/News/Article/3457014/first-in-space-laser-power-beaming-experiment-surpasses-100-days-of-successful-on-orbit-operations/>
- **Why it matters:** Documents on-orbit laser power beaming (SWELL) with quantified performance ( $\approx 1.5$  W receiver output,  $\approx 11\%$  end-to-end efficiency,  $\approx 1.45$  m link), demonstrating the principle in space beyond theory while underscoring that orbital power levels are still far from grid-material transfer. [29]

#### 10) POWER Program Selects Teams to Design Power Beaming Relays

- **Authors/Org:** [2]entity[2] ["organization", "DARPA", "us defense r&d agency"] [2]
- **Venue/type:** Government programme milestone announcement (named teams; programme goals)
- **Publication date:** Sep 2023 (7 Sep 2023)
- **Link:** <https://www.darpa.mil/news/2023/power-beaming-relay>
- **Why it matters:** Signals multi-team, funded competition to build airborne optical power relays (an “energy web”), indicating that power beaming is transitioning from isolated demos to system concepts with multiple well-capitalised engineering efforts. [30]

#### 11) DARPA program sets distance record for power beaming

- **Authors/Org:** DARPA (POWER / PRAD tests)
- **Venue/type:** Government test report / programme results announcement with quantitative performance
- **Publication date:** May 2025 (16 May 2025)
- **Link:** <https://www.darpa.mil/news/2025/darpa-program-distance-record-power-beaming>
- **Why it matters:** Reports delivery of  $>800$  W over 8.6 km for 30 seconds (and  $>1$  megajoule transferred over the campaign), a key maturity datapoint for long-range optical power beaming at meaningful power levels (though still not a commercial deployment). [31]

#### 12) Long Range WPT Flight Demonstration (Dec. 2024) – First Report

- **Authors/Org:** Japan Space Systems[32]
- **Venue/type:** Field-trial technical report / demonstration results (slides with measurement plots)
- **Publication date:** Dec 2024 (12 Dec 2024)
- **Link:** [https://www.jspacesystems.or.jp/jss/wp-content/uploads/2025/01/1stTestReport\\_2024.12.24en-1.pdf](https://www.jspacesystems.or.jp/jss/wp-content/uploads/2025/01/1stTestReport_2024.12.24en-1.pdf)
- **Why it matters:** Describes a phased-array microwave WPT flight demo using 5.8 GHz beaming from a high-speed aircraft to ground, reporting  $>5$  km vertical WPT, beam formation and directional control, and multiple flight/experiment repetitions—evidence that beam control works outside the lab and on moving platforms. [33]

### 13) Ground Receiving System and Antenna Pattern Reconstruction Method for SPS Demonstration Satellite

- **Authors/Org:** Yoshiyuki Fujino et al. (incl. JAXA[34] and Toyo University[35] affiliations in paper)

- **Venue/type:** Peer-reviewed journal article (Journal of Evolving Space Activities, open access)

- **Publication date:** 2024 (Vol. 2, Article No. 166)

- **Link:** [https://www.jstage.jst.go.jp/article/jesa/2/0/2\\_166/\\_article/-char/en](https://www.jstage.jst.go.jp/article/jesa/2/0/2_166/_article/-char/en)

- **Why it matters:** Details a proposed LEO microwave WPT demonstration framework (ground receiving station layouts for antenna-pattern reconstruction and tracking), including explicit transmitter assumptions (e.g., 5.8 GHz active phased-array concept and an 810 W transmit-power assumption), which is the kind of engineering work needed to move from concept to on-orbit tests. [36]

### 14) Demonstration of 15% Efficient Optical Wireless Power Transmission Over 1 km With Atmospheric Turbulence

- **Authors/Org:** Ochiai et al. (NTT + Mitsubishi Heavy Industries)

- **Venue/type:** Peer-reviewed experimental paper (Electronics Letters; open access)

- **Publication date:** Aug 2025

- **Link:**

[https://www.researchgate.net/publication/394319253\\_Demonstration\\_of\\_15\\_Efficient\\_Optical\\_Wireless\\_Power\\_Transmission\\_Over\\_1\\_km\\_With\\_Atmospheric\\_Turbulence](https://www.researchgate.net/publication/394319253_Demonstration_of_15_Efficient_Optical_Wireless_Power_Transmission_Over_1_km_With_Atmospheric_Turbulence)

- **Why it matters:** Reports a 1 km OWPT field experiment under strong turbulence with measured 1035 W optical transmitted and 152 W electric received (15% efficiency), using diffractive beam shaping + homogenisation + current-smoothing, and explicitly noting laser safety measures (IEC 60825-1 Class 4)—a strong PoC for practical optical links. [37]

### 15) A Compact and High-Power Rectenna Array for Wireless Power Transmission Applications

- **Authors/Org:** Huang et al.

- **Venue/type:** Peer-reviewed experimental paper (Energies; open access)

- **Publication date:** Nov 2024 (Published 29 Nov 2024)

- **Link:** <https://www.mdpi.com/1996-1073/17/23/6008>

- **Why it matters:** Demonstrates a rectenna array for MWPT with reported efficiency (47.6%) and volumetric output DC power density ( $117.6 \text{ mW/cm}^3$ ) and a verification demo powering a 12 W-rated LCD screen—direct evidence that receiver-side hardware can deliver “usable electricity” to loads in lab/benchtop demos. [38]

### 16) Enhanced laser wireless power transmission efficiency with a novel PV-TEG hybrid receiver: dual thermal management and energy recovery

- **Authors/Org:** Xian-long et al.

- **Venue/type:** Peer-reviewed experimental + simulation paper (Scientific Reports; open access)

- **Publication date:** Oct 2025 (Published 13 Oct 2025)

- **Link:** <https://www.nature.com/articles/s41598-025-14275-7>

- **Why it matters:** Shows receiver-side progress for laser WPT: a PV-TEG hybrid receiver reduces PV temperature (up to 31.94 K), improves output (reported overall improvement

25.81% over PV-only), and reports PV photoelectric conversion stabilising around ~48%—directly addressing thermal/efficiency bottlenecks highlighted in the ART. [39]

### 17) The high power electricity generation and WPT demonstration mission — Proposed first step to develop space solar power

- **Authors/Org:** Xinbin Hou et al.
- **Venue/type:** Peer-reviewed open-access paper (Space Solar Power and Wireless Transmission, Elsevier/KeAi)
- **Publication date:** Jun 2025
- **Link:** <https://www.sciencedirect.com/science/article/pii/S2950104025000276>
- **Why it matters:** Proposes a stepwise space-solar roadmap with a first mission explicitly targeting kW-level microwave WPT from LEO to ground and kW-level laser power transmission, plus validating beam control precision—evidence that the next maturity step is being engineered but is not yet demonstrated. [40]

## 3. Maturity score (1–7) and reasoning

### A) Final maturity score: 3

### B) Why this score fits the rubric (explicit evidence → rubric mapping)

**What rules out levels 1–2 (the tech is beyond theory and basic lab validation):** - There is **peer-reviewed on-orbit WPT evidence:** a space demonstration of wireless power transfer using a flexible coherent RF array operated in LEO for months and including beam-to-Earth pointing with ground detection, which exceeds “lab-only verification”. [27]

- There is **documented in-space laser power beaming** with quantified output power and efficiency over >100 days, showing that the basic laser power-beaming principle works in orbit (even if at low power and short range). [29]

- There are **high-power, long-distance terrestrial demonstrations:** optical power beaming delivering >800 W over 8.6 km (programme test) and independent peer-reviewed OWPT delivering 152 W over 1 km at 15% efficiency under strong atmospheric turbulence. [41]

Together, these directly satisfy rubric level 3’s expectation that a laboratory/prototype demonstration exists and that key functionality (beam generation, propagation, pointing, and reconversion) has been achieved in recent work.

**What is still missing to justify level 4 (PoC “meeting commercialisation requirements”) -**

**Scale gap to utility relevance:** The most credible in-space demonstrations are still **very low power** (e.g., ~1.5 W output for an orbital laser-beaming demo) or **very small experimental scale** for space-to-ground detection; none demonstrate sustained **kW–MW class space-to-ground delivered electrical power** into an operational grid interface. [42]

- **System-level readiness and operations:** Authoritative SBSP assessments highlight unresolved system blockers: spectrum/orbital-slot coordination, debris vulnerability, security, and the extreme scale of manufacturing/launch cadence required for commercial SBSP. These are not “minor engineering details”; they are front-and-centre feasibility constraints. [43]

- **Commercial-scale receiver/site build-out remains conceptual:** Pre-Phase A studies quantify very large rectenna/receiver infrastructure (e.g., tens of km<sup>2</sup> for ~1 GW-class

concepts) and still discuss safety logic for misalignment—evidence that commercial deployment sits beyond current PoC. [44]

### C) Sub-component maturity breakdown and aggregation

- **Terrestrial optical power beaming (laser → PV electricity): ~4**
- Evidence: 1 km, 1035 W optical transmitted / 152 W electric received (15%) with explicit beam-shaping and safety protocol; plus >800 W delivered at 8.6 km in programme tests. [45]
- Rationale: This is beyond lab-only; it is a functional field PoC at meaningful power. Still not at “product shipments” scale.
- **Terrestrial/airborne microwave beaming (phased array → rectenna): ~4**
- Evidence: >5 km flight demonstration of 5.8 GHz microwave WPT with beamforming and directional control on a high-speed aircraft-to-ground link; receiver hardware work showing delivery into real loads (e.g., 12 W LCD demo). [46]
- Rationale: Functional prototype in realistic geometry (moving transmitter; vertical link) exists, but not yet packaged as a commercial product with standardised deployments.
- **In-space power beaming (orbital demonstrations): ~3**
- Evidence: on-orbit laser power beaming with measured output/efficiency; peer-reviewed space WPT array demonstration with beam-to-Earth pointing/detection. [11]
- Rationale: Demonstrated prototype functionality in space, but far from high-power and far from operationalised deployment.
- **Commercial-scale SBSP delivering grid power: ~2**
- Evidence: multiple authoritative studies and roadmaps quantify system scale, economics, and blockers (launch mass/cadence; huge receivers; regulatory/security issues), indicating the concept is feasible enough to warrant pre-Phase A work but not yet demonstrated at a scaled technical level. [47]

**Aggregation to one score:** The ART as written is dominated by **space-based and utility-relevant power delivery**, not just terrestrial niche WPT. Taking a conservative average across the above ( $\approx (4 + 4 + 3 + 2) / 4 \approx 3.25$ ) and weighting toward the SBSP elements that govern the overall claim, the appropriate single score is **3** rather than 4. [48]

## ART 08.065 Advanced geothermal technology

### 1. ART extraction

- **Primary capability claimed**
- Engineer geothermal heat extraction in many more locations than conventional hydrothermal geothermal by **drilling deeper ( $\approx 5\text{--}10\text{+ km}$ ) into hotter rock** and **creating predictable heat-transfer pathways** (engineered circulation or closed-loop heat exchangers).
- Deliver **round-the-clock** high-grade heat and/or electricity using standard surface conversion equipment (e.g., binary cycles/ORC, steam cycles where temperatures allow) with modular scale-up from single well-pairs to multi-well “heat fields”.
- Reduce reliance on naturally permeable reservoirs via **reservoir engineering + high-temperature well construction + continuous sensing/control**.
- **Key sub-components / variants**
- **Engineered Geothermal Systems (EGS):** horizontal/deviated wells + stimulation (hydraulic fracturing/hydroshearing) to create permeable pathways between injector/producer wells.
- **Closed-loop geothermal systems (CLGS):** sealed wellbore loops (coaxial, U-tube, multi-lateral “radiator” geometries) extracting heat largely by conduction (and sometimes leveraging groundwater convection).

- **Superhot / supercritical geothermal:** targeting  $>\sim 374\text{ }^{\circ}\text{C}$  (often cited as “superhot rock”) to increase energy density per well, but requiring new tool/material envelopes.
- **High-temperature drilling & completion:** faster hard-rock drilling, temperature-tolerant bits, drilling fluids, and directional tools; plus casing/liners rated for extreme temperatures and stresses.
- **Well integrity materials:** corrosion-resistant casing alloys, high-temperature cement systems and zonal isolation under thermal cycling, aggressive fluids, and long duration.
- **Downhole sensing & telemetry:** fibre-optic/distributed sensing, pressure/temperature gauges, microseismic monitoring, and survivable cabling/packaging.
- **Closed-loop + surface integration:** heat exchangers, pumping/thermosiphon management, ORC/steam cycle matching, and supervisory control/digital models for thermal drawdown forecasting.
- **Risk governance:** induced seismicity management (traffic-light systems, probabilistic hazard updates), permitting pathways, and community risk acceptance.
- **What “maturity evidence” looks like for this ART**
- **Field-scale pilots** showing sustained circulation and usable heat/power output (not just lab validation).
- **Repeatable multi-well drilling and completion campaigns** with documented learning curves (reduced drilling days, cost/ft, fewer failures).
- Demonstrated **monitoring-and-control in harsh wells** (multi-well microseismic, pressure/temperature control loops; anomaly detection) with quantified performance.
- **High-temperature well integrity demonstrations** (cement/casing materials surviving months-long exposure at  $\geq 300\text{ }^{\circ}\text{C}$  and/or supercritical conditions).
- Clear **induced-seismicity risk frameworks** demonstrated in practice (adaptive traffic lights, probabilistic hazard updates).
- **Commercial pull:** PPAs/heat off-take agreements, project-finance milestones, and multiple well-capitalised actors pursuing scale projects.
- For superhot/deep variants specifically: **drilling + completion toolchains proven at  $>374\text{ }^{\circ}\text{C}$**  and at multi-km depths with credible cost trajectories.

## 2. Evidence (10–20 recent, reliable sources)

### 1) Pathways to Commercial Liftoff: Next-Generation Geothermal Power

**Authors/Org:** U.S. Department of Energy<sup>[1]</sup> (multiple DOE offices)

**Type:** Authoritative roadmap/report (government programme)

**Date:** March 2024

**Link:** <https://cdn.catf.us/wp-content/uploads/2025/06/09154348/doe-liftoff-nextgen-geothermal.pdf>

**Why it matters:** Quantifies the near-term state of “next-generation geothermal” (EGS + closed-loop), explicitly citing field-scale pilots and commercial timelines, and frames the key scaling bottlenecks: drilling cost, operability risk, and societal licence (including induced seismicity). <sup>[2]</sup>

## 2) **2025 U.S. Geothermal Market Report** (web summary + embedded figures)

**Authors/Org:** National Laboratory of the Rockies[3]

**Type:** Market monitoring / authoritative report summary (national-lab publication)

**Date:** Last updated Feb 2026

**Link:** <https://www.nlr.gov/geothermal/2025-us-geothermal-market-report>

**Why it matters:** Provides concrete, recent maturity signals: growth in U.S. geothermal nameplate capacity, a count of newly signed PPAs, documented drilling-time reductions at Utah FORGE[4] (e.g., drilling time reductions from 2020 to 2023), and named progress of next-generation projects—useful for “how close to market and scaling” assessment. [5]

## 3) **Enhanced Geothermal Shot Analysis for the Geothermal Technologies Office**

**Authors/Org:** Chad Augustine[6] et al., National Renewable Energy Laboratory[7]

**Type:** Authoritative techno-economic analysis / national lab technical report

**Date:** January 2023

**Link:** <https://docs.nrel.gov/docs/fy23osti/84822.pdf>

**Why it matters:** Establishes quantitative cost/performance targets (e.g., the Earthshot framing of \$/MWh by 2035) and documents the modelling assumptions needed for EGS to scale (flow/productivity, drilling cost reductions, plant sizing), directly supporting plausibility checks for the ART’s economics. [8]

## 4) **The Future of Enhanced Geothermal Systems in the United States**

**Authors/Org:** Lauren Boyd[9], Geothermal Technologies Office[10]

**Type:** Government programme briefing/report (authoritative)

**Date:** September 2023

**Link:** [https://www.energy.gov/sites/default/files/2023-](https://www.energy.gov/sites/default/files/2023-10/The%20Future%20of%20Enhanced%20Geothermal%20Systems%20in%20the%20United%20States.pdf)

[10/The%20Future%20of%20Enhanced%20Geothermal%20Systems%20in%20the%20United%20States.pdf](https://www.energy.gov/sites/default/files/2023-10/The%20Future%20of%20Enhanced%20Geothermal%20Systems%20in%20the%20United%20States.pdf)

**Why it matters:** Lays out the U.S. programme structure and near-term demonstration categories (including superhot/supercritical EGS), clarifying which components are treated as “demonstration-ready” vs “still R&D,” which is directly relevant to maturity scoring. [11]

## 5) **2025 Geothermal Drilling Cost Curves Update**

**Authors/Org:** Dayo Akindipe[12] and Erik Witter[13]

**Type:** Technical conference proceedings (Stanford Geothermal Workshop)

**Date:** February 2025

**Link:** <https://pangea.stanford.edu/ERE/db/GeoConf/papers/SGW/2025/Akindipe.pdf>

**Why it matters:** Uses field drilling campaigns and publicly available commercial data to revise geothermal drilling cost curves, including tabulated drilling performance and cost/ft values—direct evidence that drilling is moving along a learning curve (a core maturity constraint for advanced geothermal). [14]

## 6) **Microseismic Monitoring of a Horizontal EGS System: Case Study and State of the Art**

**Authors/Org:** Sireesh Dadi[15] et al. (Fervo Energy[16]; includes Jack Norbeck[17])

**Type:** Technical conference proceedings (Stanford Geothermal Workshop)

**Date:** February 2024

**Link:** <https://pangea.stanford.edu/ERE/db/GeoConf/papers/SGW/2024/Dadi.pdf>

**Why it matters:** Reports operational monitoring at a horizontal EGS site using multi-well fibre-optic microseismic acquisition detecting ~50,000 events over ~3 months, with traffic-

light thresholds not exceeded, and documents practical issues (e.g., fibre loss in poorly cemented areas)—strong evidence for real-world sensing/control maturity. [18]

#### 7) **Assessment of two recent hot dry rock thermal energy production projects: Utah FORGE and Blue Mountain EGS (Project Red)**

**Authors/Org:** B. Mindygaliyeva[19] et al.

**Type:** Peer-reviewed paper (Geothermics)

**Date:** 2024 (month not captured in accessible metadata)

**Link:** <https://www.sciencedirect.com/science/article/abs/pii/S0375650524001408>

**Why it matters:** Compares two contemporary HDR/EGS field efforts in a single peer-reviewed analysis, grounding plausibility claims (depth/temperature ranges, reservoir-engineering approach) and highlighting what has and has not been demonstrated in recent “modern EGS” campaigns. [20]

#### 8) **Numerical investigation of closed-loop geothermal systems in deep geothermal reservoirs**

**Authors/Org:** Mark White[21] et al.

**Type:** Peer-reviewed journal article (Geothermics; indexed via DOE/OSTI)

**Date:** January 2024

**Link:** <https://www.osti.gov/pages/biblio/2205271>

**Why it matters:** Provides a quantified design-space study (including techno-economics) showing closed-loop systems can reach competitive *heat* costs but *electricity* economics remain drilling-cost-limited—directly informing plausibility and maturity for the “sealed/closed-loop” branch of the ART. [22]

#### 9) **Numerical modelling of a deep closed-loop geothermal system: evaluating the Eavor-Loop**

**Authors/Org:** Joseph J. Kelly[23] and Christopher I. McDermott[24]; University of Edinburgh[25]

**Type:** Peer-reviewed paper (AIMS Geosciences)

**Date:** February 2022

**Link:** <https://www.aimspress.com/article/doi/10.3934/geosci.2022011>

**Why it matters:** An independent modelling-based plausibility check of deep closed-loop designs, finding headline outputs plausible under certain thermal assumptions while flagging sensitivity to subsurface conditions—useful for assessing how close CLGS variants are to robust, generalisable deployment. [26]

#### 10) **Iceland Deep Drilling Project: a Review of the Main Challenges and Implications of Drilling the Well IDDP-1**

**Authors/Org:** Agustin Garbino[27]

**Type:** Technical conference paper (GRC Transactions; superhot drilling lessons)

**Date:** October 2023

**Link:**

[https://www.researchgate.net/publication/379220950\\_Iceland\\_Deep\\_Drilling\\_Project\\_a\\_Review\\_of\\_the\\_Main\\_Challenges\\_and\\_Implications\\_of\\_Drilling\\_the\\_Well\\_IDDP-1](https://www.researchgate.net/publication/379220950_Iceland_Deep_Drilling_Project_a_Review_of_the_Main_Challenges_and_Implications_of_Drilling_the_Well_IDDP-1)

**Why it matters:** Summarises real drilling/production experience from a “magma / superhot” context (including reported ~450 °C discharge and very high enthalpy), providing hard evidence that superhot wells are physically feasible while emphasising why tool/material envelopes and corrosive fluids remain central maturity blockers. [28]

### 11) **Drilling for superhot geothermal energy: A technology gap analysis (Version 1.0)**

**Authors/Org:** Clean Air Task Force[29] and Cascade Institute[30]

**Type:** Technical report / gap analysis

**Date:** 2024

**Link:** <https://cascadeinstitute.org/wp-content/uploads/2024/09/REPORT-Drilling-for-Superhot-Geothermal-Energy-v1.0-1.pdf>

**Why it matters:** Decomposes the “superdeep + superhot” claim into specific engineering gaps (HPHT tools, bits, casing/cement, drilling fluids, well construction practices) and assigns readiness levels—directly supporting a maturity judgement for the 5–15 km, >374 °C regime. [31]

### 12) **Superhot Rock Methodology Report**

**Authors/Org:** Clean Air Task Force (methodology team)

**Type:** Technical report (resource mapping methodology; superhot rock definition and depth bins)

**Date:** June 2025 (from document path/timestamp)

**Link:** <https://cdn.catf.us/wp-content/uploads/2025/06/25170717/shr-heat-mapping-methodology.pdf>

**Why it matters:** Defines “superhot rock” operationally ( $\geq 374$  °C), separates nearer-term ( $\approx 4$ –8 km) vs medium-term ( $\approx 8$ –12 km) depth bands, and provides a repeatable mapping method—useful for evaluating the “how widespread is the resource if drilling improves?” claim. [32]

### 13) **Aluminum-Rich Cements for High Temperature Geothermal Wells**

**Authors/Org:** Tatiana Pyatina[33] and Toshifumi Sugama[34]; Brookhaven National Laboratory[35]

**Type:** Technical conference proceedings (Stanford Geothermal Workshop)

**Date:** February 2024

**Link:** <https://pangea.stanford.edu/ERE/db/GeoConf/papers/SGW/2024/Pyatina.pdf>

**Why it matters:** Reports lab and long-duration exposure tests (including months-long supercritical CO<sub>2</sub> environments) where aluminium-rich cements retain performance relative to OPC/silica degradation—directly supporting the feasibility of well integrity materials required for hotter/deeper geothermal. [36]

### 14) **Assessment of Cementitious Composites for High-Temperature Geothermal Wells**

**Authors/Org:** Pyatina et al.

**Type:** Peer-reviewed paper (Materials)

**Date:** 2024 (month not reliably extractable from the non-JS page view)

**Link:** <https://www.mdpi.com/1996-1944/17/6/1320>

**Why it matters:** Combines cyclic pressure-function testing with field exposure in a 300–350 °C geothermal well, reporting that calcium–aluminate systems outperform OPC/silica and that OPC/silica can lose mechanical properties over months—direct evidence for the durability constraint highlighted in the ART. [37]

### 15) **Updating induced seismic hazard assessments during hydraulic stimulation experiments in underground laboratories: workflow and limitations**

**Authors/Org:** Valentin Gischig[38] et al.; ETH Zürich[39] is referenced in the paper history/context

**Type:** Peer-reviewed paper (Solid Earth, Copernicus)

**Date:** 2025

**Link:** <https://se.copernicus.org/articles/16/1153/2025/>

**Why it matters:** Demonstrates an operationally relevant workflow for near-real-time induced-seismic hazard updating (including adaptive traffic-light framing), which is one of the major non-technical (but engineering-governed) scaling constraints for EGS-style reservoir creation. [40]

#### 16) Managing induced seismicity risks from enhanced geothermal systems: A good practice guideline

**Authors/Org:** Wenqin Zhou[41] et al.

**Type:** Peer-reviewed synthesis / guideline (Reviews of Geophysics)

**Date:** 2024

**Link:** <https://agupubs.onlinelibrary.wiley.com/doi/full/10.1029/2024RG000849>

**Why it matters:** Consolidates best-practice risk management for induced seismicity (a leading cause of project delay/moratoria), strengthening the plausibility of large-scale deployment *if* such governance is implemented systematically. [42]

#### 17) Forecasting induced seismicity in enhanced geothermal systems with machine learning

**Authors/Org:** S. Karimpouli[43] et al.

**Type:** Peer-reviewed paper (Geophysical Journal International)

**Date:** 2025

**Link:** <https://academic.oup.com/gji/article/242/2/ggaf155/8169887>

**Why it matters:** Provides evidence that data-driven forecasting of induced seismic response during injection is technically feasible, directly supporting the ART's claim that automated diagnostics and model-updating control loops can shift operations toward remote supervision. [44]

#### 18) Insights Into Seismicity Associated With Flexibly Operating Enhanced Geothermal System From Real-Time Distributed Acoustic Sensing

**Authors/Org:** (multi-institution team; includes industry + lab participants)

**Type:** Peer-reviewed paper (JGR: Solid Earth)

**Date:** July 2025

**Link:** <https://agupubs.onlinelibrary.wiley.com/doi/10.1029/2025JB031634?af=R>

**Why it matters:** Reports field evidence for real-time distributed sensing applied to a flexibly operated EGS context, directly connected to the “continuous regulation + anomaly flagging” maturity indicators described in the ART. [45]

### 3. Maturity score (1–7) and reasoning

**Final maturity score: 4**

#### Why this score rules out lower levels (1–3)

- **Field-scale and commercially oriented prototypes exist**, not just theory or lab-only demonstrations: DOE's liftoff report explicitly identifies next-generation geothermal pilots and frames a pathway to commercial scale. [2]

- The ecosystem has **repeatable drilling + reservoir-creation practice advancing beyond lab**, evidenced by documented improvements in drilling time and multi-well campaigns reported in the 2025 U.S. market tracking, and by drilling cost-curve updates grounded in recent field drilling datasets. [46]

- Operational monitoring/control elements that the ART claims (continuous sensing, anomaly detection hooks, traffic-light governance) are demonstrated in practice via multi-well fibre-optic microseismic monitoring and formalised induced-seismic hazard workflows. [47]

These collectively exceed “scientific principle + lab verification” and justify at least “PoC functional prototype” (level 4).

### Why the evidence is still insufficient for level 5 (and above)

- The ART’s defining leap—**routine superdeep (≈5–10+ km) access into >374 °C superhot rock with durable downhole toolchains**—is not yet shown as a repeatable, scalable, cost-bounded capability. The superhot drilling gap analysis catalogues multiple low-to-mid-TRL bottlenecks (HPHT drilling tools, well integrity, fluids, and long-duration survivability), implying the “superhot/superdeep” core remains pre-scale. [31]

- Closed-loop geothermal (a key ART variant) is still **economically and performance constrained for electricity** in many settings: peer-reviewed modelling finds competitive heat costs plausible but indicates electricity competitiveness requires major drilling cost reductions, and independent modelling highlights strong sensitivity to subsurface assumptions. [48]

- While EGS and monitoring/control are advancing rapidly, **industry-wide product delivery at increasing volumes** (levels 6–7) is not yet the norm across the “advanced geothermal” bundle; market evidence points to momentum and financing mechanisms, but scaling is still in the “prove repeatability + drive costs down” stage. [49]

### Sub-component maturity breakdown and aggregation approach

Because the ART description bundles variants with meaningfully different operating envelopes (especially the >374 °C superhot regime vs ~150–250 °C EGS/CLGS), an **average-based score** is most defensible.

- **Modern near-term EGS (horizontal drilling + multi-stage stimulation + monitoring/traffic-light governance) → ~5**
- Supported by evidence of commercial-facing pilots and rapid learning in drilling/monitoring practices (market tracking + drilling cost curve updates + field microseismic monitoring). [50]
- **Closed-loop geothermal systems (sealed loops, multi-lateral/pipe-in-pipe variants) → ~3–4**
- Strong plausibility and parameterised performance/economic modelling exist, but electricity competitiveness remains drilling-cost limited and deployment evidence is still comparatively sparse. [48]
- **Superhot / supercritical deep geothermal (>374 °C, multi-km drilling into extreme conditions) → ~2–3**
- Real-world superhot lessons exist (IDDP-1 retrospective) but the “routine superhot” toolchain is not yet mature; the primary evidence base emphasises gaps rather than reproducible commercial operations. [51]
- **High-temperature well integrity materials (cements/corrosion resistance) → ~3**

- Credible materials testing and field exposure evidence exists at 300–350 °C and under supercritical CO<sub>2</sub> environments, but system-level qualification across full well lifetimes in superhot wells is not yet established. [52]

### Aggregation to a single ART score

- Taking the above as a bundle with divergent maturity, the centre-of-mass falls at **4**: there is **clear PoC/early-commercial functionality** for the EGS branch and meaningful enabling-progress (monitoring, drilling learning curves, cement systems), but **the superdeep/superhot generalisation and broad scaling** needed for a level-5 “production prototype race” across the whole ART is not yet evidenced. [53]

## ART 08.066 Resilient microgrids

### ART extraction

- **Primary capability claimed**
- Maintain electricity supply to a defined local area during wider-grid outages or stress by operating as an islandable “local grid” that can disconnect and later resynchronise/reconnect, with minimal interruption. [1]

- Coordinate distributed energy resources (DER)—renewables, engines/gensets, and batteries—via power electronics and control software to balance supply/demand and sustain critical loads (including some black-start capability). [2]
- Improve resilience and power quality via monitoring, fast control actions, protection coordination, and operational automation—while managing constraints such as permitting/interconnection, cybersecurity, and maintenance. [3]
- **Key sub-components / sub-threads**
- **DER stack:** PV/wind + dispatchable generation + battery energy storage systems (BESS) integrated through inverters (grid-forming and grid-following). [4]
- **Microgrid controller / energy management system:** dispatch, load shedding, islanding transitions, secondary voltage/frequency control, reconnection synchronisation, and black-start sequencing. [5]
- **Sensing and data infrastructure:** SCADA/telemetry, time-synchronised measurements (e.g., event records/oscillography), and historians for operations and root-cause analysis. [6]
- **Protection & interconnection engineering:** anti-islanding measures, protection relay coordination for inverter-limited fault currents, sync-check functions, and coordination with upstream distribution equipment. [7]
- **Cybersecurity of control interfaces and smart inverters:** secure configuration, patching, interface hardening, and device/installer guidance. [8]
- **Operational readiness:** O&M, testing/commissioning practices, endurance targets, and regulatory/programme structures that enable deployment. [9]
- **Maturity indicators that would constitute strong evidence**
- **Fielded deployments** (especially critical infrastructure / community microgrids) demonstrating islanding, sustained islanded operation, and reconnection. [10]
- **Procurement-grade specifications and design criteria** that require black start, “blinkless” transitions, data logging, and secure/standardised communications. [11]
- **Independent test plans and HIL/PHIL validation** of controller functions (black start, island constraints, secondary control, reconnection). [12]
- **Standardisation/consortium performance requirements** for grid-forming inverter behaviour relevant to islanding and restoration. [13]
- **Demonstrated handling of known blockers:** inverter fault-current limitations affecting protection; cybersecurity hardening and governance; and operational procedures for maintenance and endurance. [14]

#### Evidence (10–20 recent, reliable sources)

##### 1) Microgrid Controller Survey Report: 2024 Update

- **Organisation:** Oak Ridge National Laboratory [15]
- **Venue/type:** National-lab technical report
- **Publication date:** April 2024
- **Link:** <https://info.ornl.gov/sites/publications/Files/Pub214751.pdf>
- **Why it matters:** Reviews the state of commercial microgrid controller functionality and

identifies gaps/trends, which directly informs how mature islanding/reconnection/dispatch capabilities are in real products—not just in theory. [16]

## 2) Utility Microgrid Controller Test Plan: Evaluation Method for Utility Microgrid Controllers

- **Organisation:** Electric Power Research Institute[17]
- **Venue/type:** Industry R&D technical update (test methodology)
- **Publication date:** December 2023
- **Link:** <https://restservice.epri.com/publicdownload/000000003002028385/0/Product>
- **Why it matters:** Defines concrete test cases and performance metrics for controller functions including island operations, **black start**, and **synchronised reconnection**, indicating that controller evaluation is moving into repeatable, deployment-oriented practice. [18]

## 3) Controller Hardware-in-the-Loop Evaluation of a Microgrid Controller for a Microgrid System with Multiple Grid-Forming Inverters (Preprint)

- **Organisation:** National Renewable Energy Laboratory[19]
- **Venue/type:** National-lab conference paper / preprint (controller-HIL validation)
- **Publication date:** September 2024 (conference presentation noted for October 2024)
- **Link:** <https://docs.nrel.gov/docs/fy24osti/89074.pdf>
- **Why it matters:** Demonstrates controller-managed islanded operation using multiple DER types and explicitly exercises a **black-start sequence** (BESS energisation and staged load/DER bring-up), providing technical evidence that advanced microgrid control functions can be validated in HIL environments. [20]

## 4) Unified Facilities Criteria: Resilient Installation Microgrid Design (UFC 3-550-04)

- **Organisation:** United States Department of Defense[21]
- **Venue/type:** Authoritative engineering/design criteria (military facilities)
- **Publication date:** March 2024
- **Link:** [https://www.wbdg.org/FFC/DOD/UFC/ufc\\_3\\_550\\_04\\_2024.pdf](https://www.wbdg.org/FFC/DOD/UFC/ufc_3_550_04_2024.pdf)
- **Why it matters:** Treats resilient microgrids as a procurement-ready capability; explicitly states that installation microgrids **must be capable of black start** and discusses islanding formation and operational requirements—strong evidence of real-world engineering feasibility and institutional adoption. [22]

## 5) UFGS 26 37 13: Microgrid Control System

- **Organisation:** (U.S. federal facilities guide specification; issued via WBDG)
- **Venue/type:** Procurement specification for microgrid control systems
- **Publication date:** February 2024
- **Link:** <https://www.wbdg.org/FFC/DOD/UFGS/UFGS%2026%2037%2013.pdf>
- **Why it matters:** Specifies implementation-level requirements for alarms, health status, metering, historian data, dispatch modes (including resiliency dispatch), and reconnection/black-start test scenarios—evidence that “dense sensing + control dashboards + automation” is being concretely required in procurements. [23]

## 6) UNIFI Specifications for Grid-Forming Inverter-Based Resources: Version 2 (UNIFI-2024-2-1)

- **Organisation:** UNIFI Consortium[24]

- **Venue/type:** Research consortium specification / requirements document
- **Publication date:** March 2024 (release date 21 March 2024)
- **Link:** <https://www.nrel.gov/docs/fy24osti/89269.pdf>
- **Why it matters:** Codifies vendor-agnostic performance requirements for grid-forming inverter-based resources, including sections explicitly addressing **intentional islanding** and **black start/system restoration**, supporting the plausibility of inverter-enabled resilient microgrids and signalling accelerating standardisation. [25]

#### 7) White Paper: Grid Forming Functional Specifications for BPS-Connected Battery Energy Storage Systems

- **Organisation:** North American Electric Reliability Corporation[26]
- **Venue/type:** Reliability/standards-adjacent white paper
- **Publication date:** September 2023
- **Link:** [https://www.nerc.com/globalassets/our-work/reports/white-papers/white\\_paper\\_gfm\\_functional\\_specification.pdf](https://www.nerc.com/globalassets/our-work/reports/white-papers/white_paper_gfm_functional_specification.pdf)
- **Why it matters:** Provides functional performance framing and verification approaches for grid-forming BESS, noting that some smaller islanded systems already face these challenges and detailing verification tests—relevant to microgrid stability, fault response expectations, and reconnection readiness. [27]

#### 8) Protection of 100% Inverter-dominated Power Systems with Grid-Forming Inverters and Protection Relays – Gap Analysis and Expert Interviews (SAND2024-04848)

- **Organisation:** Sandia National Laboratories[28]
- **Venue/type:** National-lab technical report (gap analysis + expert interviews; public copy available)
- **Publication date:** April 2024
- **Link:** [https://www.researchgate.net/publication/379952862\\_Protection\\_of\\_100\\_Inverter-dominated\\_Power\\_Systems\\_with\\_Grid-Forming\\_Inverters\\_and\\_Protection\\_Relays\\_-\\_Gap\\_Analysis\\_and\\_Expert\\_Interviews](https://www.researchgate.net/publication/379952862_Protection_of_100_Inverter-dominated_Power_Systems_with_Grid-Forming_Inverters_and_Protection_Relays_-_Gap_Analysis_and_Expert_Interviews)
- **Why it matters:** Directly addresses one of the ART's hardest constraints—**protection coordination** under grid-forming inverter fault behaviour—by documenting gaps and priority issues (e.g., relay response to inverter-limited currents), indicating where maturity is still bounded. [29]

#### 9) Anti-Islanding Techniques for Integration of Inverter-Based Distributed Energy Resources to the Electric Power System

- **Authors:** Ênio Costa Resende[30] et al.
- **Venue/type:** Peer-reviewed paper (IEEE Access)
- **Publication date:** January 2024 (published 23 January 2024; current version 6 February 2024)
- **Link:** <https://osuva.uwasa.fi/bitstreams/4e7124e5-7227-4081-b5a3-30cd6a47a399/download>
- **Why it matters:** Surveys practical anti-islanding approaches (passive/active/remote/hybrid/ML) and highlights risks such as out-of-phase reconnection—direct evidence that engineering methods exist but must be selected/tuned to enable safe intentional islanding in resilient microgrids. [31]

#### 10) Reconnection of MV Microgrid with Universal Grid-forming Inverter-based Resources (Accepted Manuscript; IET Conference Proceedings / MEDPOWER 2024)

- **Authors:** Hannu Laaksonen[32]; Nikos Hatziaargyriou[33]
- **Venue/type:** Peer-reviewed conference proceedings (postprint/accepted manuscript)
- **Publication date:** 2025 (conference proceedings volume 2024)
- **Link:** <https://osuva.uwasa.fi/bitstreams/61fee869-6e8c-4957-8a4d-74e97dc1ef9d/download>
- **Why it matters:** Provides concrete reconnection stability findings for a medium-voltage microgrid using a specific synchronisation method (U-FLL), reporting stable reconnection under large phase-angle differences ( $\pm 140\text{--}180^\circ$  depending on case) in PSCAD studies—relevant to the “reconnection with minimal interruption” claim. [34]

#### 11) Fiscal Year 2021 Isolated Grids and Grid-Connected Turbine Reference Systems; Microgrids, Infrastructure Resilience, and Advanced Controls Launchpad (MIRACL)

- **Organisation:** United States Department of Energy[35] national-lab programme report (multi-lab)
- **Venue/type:** National-lab technical report
- **Publication date:** July 2022
- **Link:** <https://docs.nrel.gov/docs/fy22osti/81792.pdf>
- **Why it matters:** Discusses microgrid resilience services and explicitly describes how black start can be provided by renewables through a **grid-forming inverter plus integrated battery storage**, supporting engineering plausibility for black-start capable microgrids beyond diesel-only designs. [36]

#### 12) Cybersecurity for Smart Inverters: Guidelines for Residential and Light Commercial Solar Energy Systems (NIST IR 8498)

- **Organisation:** National Institute of Standards and Technology[37]
- **Venue/type:** Government technical guidance with device testing
- **Publication date:** December 2024
- **Link:** <https://nvlpubs.nist.gov/nistpubs/ir/2024/NIST.IR.8498.pdf>
- **Why it matters:** Provides seven cybersecurity guidelines and reports testing of **five** example smart inverters, while recommending manufacturer capabilities to support secure installation/operation—directly relevant to the ART’s cybersecurity constraint around inverter/control interfaces. [38]

#### 13) Cybersecurity of distributed energy resource systems in the smart grid: A survey

- **Authors:** Juanwei Chen[39] et al.
- **Venue/type:** Peer-reviewed survey (Applied Energy, open access)
- **Publication date:** April 2025 (Volume 383, 1 April 2025)
- **Link:** <https://www.sciencedirect.com/science/article/pii/S0306261925000947>
- **Why it matters:** Synthesises DER cybersecurity requirements/standards and defence strategies (prevention/detection/mitigation) and maps research gaps—evidence that scaling resilient microgrids requires systematic cyber risk management across multi-stakeholder DER coordination. [40]

#### 14) Microgrid Handbook for Army Resilience: A Technical Review (PNNL-38494)

- **Organisation:** Pacific Northwest National Laboratory[41]
- **Venue/type:** National-lab technical review / handbook
- **Publication date:** October 2025

- **Link:** <https://www.osti.gov/servlets/purl/2997694>
- **Why it matters:** Provides an end-to-end technical view of microgrid components, monitoring/control, O&M, and explicitly treats microgrid cybersecurity (including processes such as security authorisation), reinforcing that resilience is as much operations and governance as hardware capability. [42]

#### 15) State Microgrid Policy, Programmatic, and Regulatory Framework

- **Organisations:** National Association of Regulatory Utility Commissioners[43]; National Association of State Energy Officials[44]
- **Venue/type:** Multi-stakeholder policy/regulatory framework (with DOE support)
- **Publication date:** August 2023
- **Link:** <https://www.naseo.org/data/sites/1/documents/publications/Final%20Microgrid%20Framework.pdf>
- **Why it matters:** Documents how state agencies and regulators are actively creating programmes/rules for microgrid deployment and interconnection, reflecting real-world maturation drivers and constraints (safety, reliability, market structure, regulatory approvals). [45]

#### 16) Black start from renewable energy resources: Review and a case study of Great Britain

- **Authors:** Zhongmei Pan[46] et al.
- **Venue/type:** Peer-reviewed review + case study (Renewable and Sustainable Energy Reviews, open access)
- **Publication date:** March 2025 (Volume 209)
- **Link:** <https://www.sciencedirect.com/science/article/pii/S1364032124008694>
- **Why it matters:** Reviews black-start control/planning with renewables and discusses “multiple power islands” restoration concepts using findings from innovation projects in the United Kingdom[47]—highly relevant to microgrids’ black-start and restoration plausibility beyond conventional generators. [48]

#### 17) Enhancing resilience: Climate-proofing power infrastructure

- **Organisation:** International Renewable Energy Agency[49]
- **Venue/type:** International agency technical report
- **Publication date:** December 2025
- **Link:** [https://www.irena.org/-/media/Files/IRENA/Agency/Publication/2025/Dec/IRENA\\_TEC\\_Enhancing\\_resilience\\_power\\_infrastructure\\_2025.pdf](https://www.irena.org/-/media/Files/IRENA/Agency/Publication/2025/Dec/IRENA_TEC_Enhancing_resilience_power_infrastructure_2025.pdf)
- **Why it matters:** Summarises how grid-forming inverters plus storage can support standalone operation and provide black-start services, while noting ongoing international trials—useful corroboration that enabling technologies for resilient microgrids are seen as deployable resilience tools globally. [50]

#### 18) MICROGRIDS: Benefits, metrics, applications, and state-level programmes (SAND2025-15190PE)

- **Organisation:** United States[51] national laboratory presentation (Sandia)
- **Venue/type:** National-lab technical briefing / slide deck
- **Publication date:** November 2025 (dated 14 November 2025)
- **Link:**

[https://www.sandia.gov/app/uploads/sites/273/2025/12/Microgrids\\_Reliability\\_StatePrograms\\_12012025.pdf](https://www.sandia.gov/app/uploads/sites/273/2025/12/Microgrids_Reliability_StatePrograms_12012025.pdf)

- **Why it matters:** Cites a microgrid installation database count (461 installations) and provides deployment-oriented discussion of outage duration, endurance targets (including a DoD 30-day endurance target), and cost scaling—direct maturity evidence that microgrids are deployed and operationally framed as reliability/resilience infrastructure. [52]

### **Maturity score (1–7) and reasoning**

#### **Final maturity score: 6**

Resilient microgrids (as a system bundle) best fit level **6**: deployments and products exist and are expanding, but scaling remains constrained by site-specific engineering, protection/cybersecurity maturity limits, and regulatory complexity.

#### **Why the evidence rules out lower maturity levels (≤5)**

- The technology is not just laboratory or single-site prototype work: procurement-grade criteria explicitly require core resilience functions (e.g., black start and islanding formation) and specify microgrid control system capabilities, data collection, and operational functions—strong evidence of deployable, repeatable engineering practice rather than PoC. [53]

- Independent test/evaluation methods exist for commercial/utility microgrid controllers (including black start and reconnection test plans), indicating post-PoC operational validation and readiness activities. [54]

- Controller/HIL studies explicitly exercise black-start sequencing and islanded operation in structured test settings, which is typical of late-stage validation before/alongside field roll-out. [55]

- Deployment-maturity signals appear in compiled deployment counts and operational framing (e.g., hundreds of installations referenced and state-level programmes targeting resilience outcomes). [10]

#### **What is still missing to justify the next higher level (7)**

- Level 7 implies broad, rising demand with strongly self-sustaining growth and “competing products” scaling across wide customer segments. While deployments are real and growing, the evidence here still shows that major parts of the system are **integration-heavy and bespoke** (procurement specs emphasise extensive data/historian requirements, protection studies, and endurance/dispatch configuration), which tends to slow industrial-scale commoditisation. [56]

- Key blockers remain active research/standardisation topics—especially **protection coordination in inverter-dominated fault conditions** and **DER/microgrid cybersecurity governance**—suggesting that “fully mature resilient microgrids” with uniformly high automation and assured safety/security across contexts are not yet a solved, standardised product category. [57]

### **Evidence-to-rubric mapping**

- **Score-anchoring evidence for level 6 (delivered systems + expanding applications)**
- Procurement/design standards requiring black start and defining islanding/reconnection architectures: UFC 3-550-04 and UFGS 26 37 13. [11]

- Utility/industry evaluation methodology for microgrid controllers and HIL validation of black-start/island operation: EPRI test plans and NREL controller-HIL paper. [12]
- Deployment-scale indicators: national-lab briefing citing hundreds of installations and ongoing state programmes. [10]
- **Sub-component maturity snapshot (bundle-aware)**
- **Microgrid controller / EMS functions (islanding, dispatch, reconnection, basic black start sequencing) → ~6** (commercial + test-plan standardisation + HIL validation). Key sources: EPRI controller test plan; NREL controller-HIL; ORNL controller survey. [58]
- **Grid-forming inverter capability enabling stable islanded operation / restoration → ~5–6** (formalised performance requirements and major standardisation push; still evolving). Key sources: UNIFI specifications; NERC functional specs; IRENA resilience report. [59]
- **Protection coordination in inverter-dominated microgrids (self-healing, relay behaviour under limited fault current) → ~4–5** (clear gaps and ongoing work; still a maturity limiter). Key source: Sandia gap analysis report. [29]
- **Cybersecurity of inverters and microgrid/DER interfaces → ~4–5** (actionable guidelines and testing exist, but sector-wide assurance/certification and implementation consistency remain a bottleneck). Key sources: NIST IR 8498; Applied Energy DER cybersecurity survey; PNNL microgrid handbook. [8]

**Aggregation logic:** The overall ART score is set to **6** (not the maximum of subcomponents) because resilient microgrids are system-of-systems deployments; the operational value depends on the weakest links (protection coordination, cybersecurity governance, and site-specific interconnection engineering). [60]

## Group 9 - Bio-engineering & Life-Science Technologies

### ART 09.067 Next-Generation Gene Editing

#### ART extraction

#### Primary capability claimed by the ART

- Programmable “molecular repair tools” that can change DNA (and sometimes RNA) with tighter control over **where**, **what**, and **how** edits occur, reducing unintended edits and improving reliability across cell types. [1]
- A broader editing menu than “cut-and-replace”: single-nucleotide corrections, small indels, gene switching (up/down regulation without sequence rewrite), and multiplex edits coordinated across multiple genomic sites. [2]
- A software-like design-and-validate loop supported by measurement standards: predictable performance, sequencing-based verification, standardised off-target/quality metrics, and transient “payloads” that degrade after editing to reduce risk. [3]

#### Key sub-components / variants implied by the ART

- **Precision editors** for “small” changes: base editors and prime editors (nuclease-independent or reduced-break approaches) intended to reduce by-products from double-strand breaks. [4]
- **Large-insert / gene-sized writing tools** (e.g., CRISPR-directed integrases; CRISPR-associated transposases) for targeted, kilobase-to-gene scale insertion without relying on classical HDR. [5]
- **Gene switching / epigenome editing** (durable silencing or reversible control) via targeted chromatin/DNA methylation changes rather than sequence edits. [6]
- **Delivery engineering** tailored to tissue/context (e.g., LNPs, AAV, engineered virus-like particles), with an emphasis on transient expression/forms (RNPs, mRNA) to reduce integration and long-term exposure. [7]

- **Off-target and QC metrology:** sensitive, unbiased off-target mapping methods; inter-lab studies, reference materials, and regulator expectations for safety/quality documentation. [8]
- **Clinical translation & governance:** regulatory guidance for genome-editing products, and real-world approvals for genome-editing medicines that demonstrate manufacturability, clinical monitoring, and post-market obligations. [9]

#### What maturity indicators would count as strong evidence

- Robust **in vivo editing** in therapeutically relevant tissues at clinically meaningful levels, with quantified safety signals (off-target, toxicity, immune effects) and durability where relevant. [10]
- Demonstrations of **new editing modalities** (e.g., gene-sized insertion without DSBs) achieving workable efficiencies in human cells and/or animals. [11]
- **Standardised measurement** activity: regulator guidance defining expected safety/quality packages; inter-lab studies; reference materials; methods that are demonstrably sensitive and reproducible. [12]
- Clear **translation signals:** IND-enabling packages, first-in-human treatments, and/or formal product authorisations by multiple regulators/regions. [13]

#### 2. Evidence (10–20 recent, reliable sources)

##### Large-insert and “gene-sized” editing modalities

##### 1) Drag-and-drop genome insertion of large sequences without double-strand DNA cleavage using CRISPR-directed integrases (PASTE)

- Authors/Org: M.T.N. Yarnall et al.
- Venue/type: Nature Biotechnology (peer-reviewed experimental paper)
- Publication date: **Nov 2022** (24 Nov 2022)
- Link: <https://www.nature.com/articles/s41587-022-01527-4> [14]
- Why it matters: Demonstrates targeted integration of payloads up to ~36 kb in human cell lines, primary T cells, and non-dividing primary human hepatocytes using a Cas9 nickase–RT–serine integrase fusion, supporting plausibility of “repair-tool” style gene insertion without DSB reliance. [15]

##### 2) Targeted DNA integration in human cells without double-strand breaks using CRISPR-associated transposases (Type I-F CASTs)

- Authors/Org: G.D. Lampe et al.
- Venue/type: Nature Biotechnology (peer-reviewed experimental paper)
- Publication date: **Mar 2023** (29 Mar 2023)
- Link: <https://www.nature.com/articles/s41587-023-01748-1> [16]
- Why it matters: Reconstitutes multi-component CAST machinery in human cells and reports large-DNA integration without DSBs, including “orders of magnitude” enhancement from bacterial ClpX, indicating rapid engineering progress but still research-stage complexity. [16]

##### 3) Programmable gene insertion in human cells with a laboratory-evolved CRISPR-associated transposase (evoCAST)

- Authors/Org: I.P. Witte et al.
- Venue/type: Science (peer-reviewed experimental paper; PubMed abstract accessible)
- Publication date: **May 2025** (15 May 2025)

- Link: <https://pubmed.ncbi.nlm.nih.gov/40373119/> [17]
- Why it matters: Uses continuous evolution (PACE) to create CAST variants with **>200×** improved integration activity and reports **~10–30%** integration efficiencies of kilobase cargoes across 14 genomic target sites in human cells, a major maturity signal for gene-sized “writing” tools. [17]

#### **Precision editing of small variants and reliability improvements**

#### **4) High-fidelity PAMless base editing of hematopoietic stem cells to treat chronic granulomatous disease**

- Authors/Org: V. Bzhilyanskaya et al.
- Venue/type: Science Translational Medicine (peer-reviewed experimental/translation paper; PMC full text)
- Publication date: **Oct 2024** (16 Oct 2024)
- Link: <https://pmc.ncbi.nlm.nih.gov/articles/PMC11753194/> [18]
- Why it matters: Shows PAMless ABE8e-SpRY achieves **up to 70% correction** of a prototypical CGD mutation in human HSPCs with “minimal off-target or bystander edits,” persistence post-transplant in mice, and states IND-enabling work supporting a first-in-human clinical trial. [18]

#### **5) Patient-Specific In Vivo Gene Editing to Treat a Rare Genetic Disease**

- Authors/Org: K. Musunuru et al.
- Venue/type: The New England Journal of Medicine (peer-reviewed case report; PubMed abstract accessible)
- Publication date: **May/Jun 2025** (Epub 15 May 2025; issue 12 Jun 2025)
- Link: <https://pubmed.ncbi.nlm.nih.gov/40373211/> [19]
- Why it matters: Reports an individually customised, LNP-delivered base-editing therapy given to a patient (two infusions at ~7 and 8 months) with no serious adverse events in early follow-up—strong evidence that “bespoke, high-end” next-gen editing workflows can reach real clinical use under regulatory oversight. [19]

#### **6) Engineered base editors with reduced bystander editing through directed evolution**

- Authors/Org: R.M. Perrotta et al.
- Venue/type: Nature Biotechnology (peer-reviewed experimental paper)
- Publication date: **Dec 2025** (18 Dec 2025)
- Link: <https://www.nature.com/articles/s41587-025-02937-w> [20]
- Why it matters: Integrates gRNA engineering, directed evolution, and protein-language-model design to reduce bystander editing while maintaining efficiency—directly aligned with the ART’s “tighter control” and incremental engineering pathway. [21]

#### **Delivery modalities and transient “payloads”**

#### **7) Lung and liver editing by lipid nanoparticle delivery of a stable CRISPR–Cas9 ribonucleoprotein**

- Authors/Org: K. Chen et al.
- Venue/type: Nature Biotechnology (peer-reviewed experimental paper)
- Publication date: **Oct 2024** (16 Oct 2024)
- Link: <https://www.nature.com/articles/s41587-024-02437-3> [22]
- Why it matters: Reports tissue-selective LNP formulations delivering a thermostable Cas9 RNP achieving **16–37%** editing in liver/lung after a single IV injection in reporter mice and

~19% editing of a disease gene in lung, supporting plausible scaling of transient, non-viral delivery beyond liver. [22]

### **8) Safer and efficient base editing and prime editing via ribonucleoproteins delivered through optimized lipid-nanoparticle formulations**

- Authors/Org: R. Hołubowicz et al.
- Venue/type: Nature Biomedical Engineering (peer-reviewed experimental paper)
- Publication date: **Nov 2024** (28 Nov 2024)
- Link: <https://www.nature.com/articles/s41551-024-01296-2> [23]
- Why it matters: Shows microfluidically mixed, chemically defined LNPs encapsulating base/prime editor RNPs can yield >300× in vivo editing-efficiency improvements over naked RNP delivery and reports “no detectable off-target edits,” directly addressing reliability + delivery bottlenecks. [24]

### **9) Engineered virus-like particles for transient delivery of prime editor ribonucleoprotein complexes in vivo**

- Authors/Org: M. An et al.
- Venue/type: Nature Biotechnology (peer-reviewed experimental paper)
- Publication date: **Jan 2024** (08 Jan 2024)
- Link: <https://www.nature.com/articles/s41587-023-02078-y> [25]
- Why it matters: Develops prime editor eVLPs delivering prime editor proteins + guide RNAs as transient RNPs, with **65–170×** higher editing than prior constructs and functional rescue signals in mouse retinal disease models—evidence of maturing transient payload packaging beyond LNPs. [25]

### **10) Efficient prime editing in mouse brain, liver and heart with dual AAVs**

- Authors/Org: J.R. Davis et al.
- Venue/type: Nature Biotechnology (peer-reviewed experimental paper)
- Publication date: **May 2023** (04 May 2023)
- Link: <https://www.nature.com/articles/s41587-023-01758-z> [26]
- Why it matters: Reports dual-AAV prime editor systems achieving up to **42%** editing in cortex, **46%** in liver, and **11%** in heart in mice, with “no detectable off-target effects” in tested contexts—strong plausibility evidence that prime editing can reach hard-to-edit tissues with clinically familiar vectors. [26]

### **Editing optimisation, design rules, and outcome prediction**

### **11) Systematic optimization of prime editing for the efficient functional correction of CFTR F508del in human airway epithelial cells**

- Authors/Org: A.A. Sousa et al.
- Venue/type: Nature Biomedical Engineering (peer-reviewed experimental/engineering paper)
- Publication date: **Jul 2024** (10 Jul 2024)
- Link: <https://www.nature.com/articles/s41551-024-01233-3> [27]
- Why it matters: Combines multiple engineering levers (e.g., PEmax/PE6 variants, engineered guides, transient mismatch-repair modulation) to raise F508del correction from <**0.5%** to **58%** in immortalised bronchial cells and **25%** in patient-derived airway cells, with edit-to-indel ratios exceeding nuclease HDR by ~3.5× and functional rescue to >50% of WT—clear PoC-level performance progress. [28]

## 12) Multimodal scanning of genetic variants with base and prime editing

- Authors/Org: (first author not shown in excerpt)
- Venue/type: Nature Biotechnology (peer-reviewed experimental paper)
- Publication date: **Nov 2024** (20 Nov 2024)
- Link: <https://www.nature.com/articles/s41587-024-02439-1> [29]
- Why it matters: Uses pooled base- and prime-editing guide libraries to install “tens of thousands” of variants across EGFR in multiple cell lines, demonstrating the high-throughput design→test→learn loop implied by the ART (software-like iteration backed by sequencing readouts). [29]

### Gene switching via epigenome editing (durable, reversible control)

## 13) Durable and efficient gene silencing in vivo by hit-and-run epigenome editing

- Authors/Org: M.A. Cappelluti et al.
- Venue/type: Nature (peer-reviewed experimental paper)
- Publication date: **Feb 2024** (28 Feb 2024)
- Link: <https://www.nature.com/articles/s41586-024-07087-8> [30]
- Why it matters: Demonstrates transient delivery of epigenome editors via LNP mRNA can produce long-lived gene silencing in vivo (PCSK9 nearly 1 year; persistence through liver regeneration), underpinning the ART’s “gene switching without rewriting sequence” pathway. [30]

## 14) A potent epigenetic editor targeting human PCSK9 for durable reduction of low-density lipoprotein cholesterol levels

- Authors/Org: F. Tremblay et al.
- Venue/type: Nature Medicine (peer-reviewed preclinical paper)
- Publication date: **Feb 2025** (10 Feb 2025)
- Link: <https://www.nature.com/articles/s41591-025-03508-x> [31]
- Why it matters: Reports a single dose of LNP mRNA encoding an epigenetic editor drives near-complete PCSK9 silencing in mice for ≥1 year and, in cynomolgus monkeys, ~90% PCSK9 protein reduction with ~70% LDL-C reduction—high-value maturity signal for scalable, non-sequence “switch-off” therapeutics (still preclinical). [31]

## 15) Programmable epigenome editing by transient delivery of CRISPR epigenome editor ribonucleoproteins (RENDER)

- Authors/Org: D. Xu et al.
- Venue/type: Nature Communications (peer-reviewed experimental paper)
- Publication date: **Aug 2025** (26 Aug 2025)
- Link: <https://www.nature.com/articles/s41467-025-63167-x> [32]
- Why it matters: Presents an eVLP-based platform for transient delivery of large epigenome-editor RNPs (CRISPRi/CRISPRoff and others) with durable silencing across human cell types including primary T cells, supporting the feasibility of transient, controllable gene-regulation payloads. [32]

### Off-target detection, QC, standards, and governance

## 16) Sensitive and unbiased genome-wide profiling of base-editor-induced off-target activity using CHANGE-seq-BE

- Authors/Org: C.R. Lazzarotto et al.
- Venue/type: Nature Biotechnology (peer-reviewed methods/experimental paper)

- Publication date: **Jan 2026** (02 Jan 2026)
- Link: <https://www.nature.com/articles/s41587-025-02948-7> [33]
- Why it matters: Introduces a sensitive, unbiased off-target discovery workflow for base editors and reports base-editor off-target profiles can differ substantially from nuclease methods (e.g., **98.8%** of validated off-target sites unique to ABE8e vs Cas9 nuclease in one comparison), illustrating why next-gen editors need editor-specific safety metrology to mature. [34]

### **17) Human Gene Therapy Products Incorporating Human Genome Editing: Guidance for Industry**

- Authors/Org: U.S. Food and Drug Administration[35] (CBER)
- Venue/type: Regulator guidance (authoritative report)
- Publication date: **Jan 2024**
- Link: <https://www.fda.gov/media/156894/download> [36]
- Why it matters: Sets explicit expectations for IND packages spanning product design, manufacturing/testing, nonclinical safety, and clinical trial design, and highlights risks such as off-target editing and unintended on-target consequences—evidence of governance maturity and a clearer translation pathway for new editors. [37]

### **18) Measurement solutions and standards for advanced therapy (meeting report)**

- Authors/Org: L. Wang et al.; National Institute of Standards and Technology[38]
- Venue/type: Meeting report in Molecular Therapy: Methods & Clinical Development (authoritative standards/roadmap evidence)
- Publication date: **Mar 2024** (published 01 Mar 2024)
- Link: [https://tsapps.nist.gov/publication/get\\_pdf.cfm?pub\\_id=957436](https://tsapps.nist.gov/publication/get_pdf.cfm?pub_id=957436) [39]
- Why it matters: Documents inter-laboratory studies, working groups, and cross-sector workshops (including gene-delivery system metrology and genome-editing measurement efforts), signalling an emerging standardisation infrastructure needed for scalable, auditable editing. [39]

### **19) Variability in genome-engineering source materials: consider your starting point**

- Authors/Org: S. Patange et al.; National Institute of Standards and Technology[38]
- Venue/type: Synthetic Biology (peer-reviewed perspective with engineering framework)
- Publication date: **Mar 2023** (advance access 10 Mar 2023)
- Link: [https://tsapps.nist.gov/publication/get\\_pdf.cfm?pub\\_id=933768](https://tsapps.nist.gov/publication/get_pdf.cfm?pub_id=933768) [40]
- Why it matters: Identifies how genotype/phenotype variability and cell heterogeneity can confound genome engineering outcomes and provides a cause-and-effect framework—directly relevant to the ART's emphasis on repeatability, QC, and predictable outcomes across cell states. [41]

### **Market and regulatory maturity signals (cross-region)**

### **20) CASGEVY product approval information (FDA biologics page)**

- Authors/Org: U.S. Food and Drug Administration[35]; manufacturer listed as Vertex Pharmaceuticals[42]
- Venue/type: Regulator product page (authoritative product/regulatory evidence)
- Publication date: Page content current **Feb 2024** (content current as of 21 Feb 2024)
- Link: <https://www.fda.gov/vaccines-blood-biologics/casgev> [43]
- Why it matters: Confirms an approved genome-editing medicine exists with defined

indications, manufacturer, and regulatory documentation—evidence that genome editing has crossed into delivered products (even if “next-gen” modalities vary in maturity). [43]

## **21) MHRA authorisation announcement for Casgevy (world-first gene-editing therapy) with interim trial readouts**

- Authors/Org: Medicines and Healthcare products Regulatory Agency[44]
- Venue/type: Regulator press release with trial outcomes (authoritative)
- Publication date: **Nov 2023** (16 Nov 2023)
- Link: <https://www.gov.uk/government/news/mhra-authorises-world-first-gene-therapy-that-aims-to-cure-sickle-cell-disease-and-transfusion-dependent-thalassemia> [45]
- Why it matters: Provides regulator-published interim efficacy figures (e.g., **97%** free of severe pain crises for  $\geq 12$  months in eligible SCD participants; **93%** transfusion-independent for  $\geq 12$  months in eligible TDT participants) and confirms post-authorisation monitoring expectations—strong maturity signal for clinical adoption of genome editing. [45]

## **22) Casgevy EPAR (EU) indicating conditional marketing authorisation date**

- Authors/Org: European Medicines Agency[46]
- Venue/type: Regulator EPAR (authoritative)
- Publication date: **Feb 2024** (conditional marketing authorisation valid throughout EU on 9 Feb 2024; EPAR first published 28 Feb 2024)
- Link: <https://www.ema.europa.eu/en/medicines/human/EPAR/casgevy> [47]
- Why it matters: Independent regional authorisation confirms multi-jurisdiction regulatory acceptance for genome-editing therapeutics, supporting plausibility of future approvals for newer editor classes once safety/CMC evidence is adequate. [47]

## **3. Maturity score (1–7) and reasoning**

### **Final maturity score: 5**

The ART sits at **level 5** because (i) genome editing is already clearly beyond purely academic demonstrations (ruling out levels 1–3), and (ii) multiple editor classes and enabling technologies have crossed strong PoC thresholds with rapid iteration and translation signals, but (iii) the specific “next-generation” modalities (base/prime/epigenome editing and gene-sized insertions) are not yet broadly commercialised as routine, scaled products across many indications (so level 6 is not yet justified). [48]

### **Evidence-to-rubric mapping**

#### **What evidence rules out lower levels (why it is $\geq 4$ ):**

- There are multiple peer-reviewed in vivo demonstrations showing therapeutically relevant editing magnitudes and/or durable functional effects (e.g., prime editing in mouse cortex/liver/heart up to 42%/46%/11%; LNP-delivered stable Cas9 RNP achieving 16–37% organ editing; epigenetic editing producing near-year durability in vivo). [49]
- Several “previously blocking” bottlenecks highlighted in the ART—especially delivery and control—have direct experimental responses: transient RNP delivery via eVLPs (prime editing) and chemically defined LNP formulations that boost potency dramatically while emphasising low/no detectable off-target edits in stated assays. [50]
- For base editing, translation maturity is strongly signalled by IND-enabling work with quantitative correction in patient-relevant cell types (up to 70% mutation correction in HSPCs

with minimal off-target/bystander edits) and a published patient-specific in vivo base-editing intervention under regulatory approval. [51]

Together, these exceed “lab prototype only” (level 3) and meet PoC-style functional demonstrations (level 4). [52]

#### **Why level 5 (and not just level 4):**

- Rapidly improving capabilities for gene-sized insertion and DSB-free integration now reach ~10–30% efficiencies in human cells for kilobase cargoes (evoCAST), and PASTE demonstrates ~36 kb targeted integration across multiple human contexts—evidence of fast-paced post-PoC engineering with a credible path toward therapeutic/industrial prototypes. [53]

- The ecosystem is moving into scaling disciplines: regulator guidance targeted specifically at genome-editing products (manufacturing/testing, safety, clinical design) and government metrology/standards programmes documenting inter-lab studies and standardisation for gene delivery and editing measurement. [54]

- Cross-region authorisations of a genome-editing medicine (evidence of delivery to real patients under formal regulatory regimes) demonstrate that at least some genome-editing modalities have cleared major commercialisation gates, and those pathways can be re-used by next-generation editors as they mature. [55]

#### **What is still missing to justify level 6:**

- Broad, routine delivery of **next-generation editors** (base/prime/epigenome editors and gene-sized insertion tools) as marketed products with increasing volumes, not just in isolated cases or preclinical models; today’s strongest “delivered product” evidence is an approved nuclease-based genome-editing therapy rather than widespread approvals of base/prime/epigenome tools. [56]

- More public evidence of industrial-scale manufacturing expansion, consistent multi-site clinical trial outcomes for the newer editor classes, and mature reference standards/qualification frameworks widely adopted for editor-specific off-target and long-term safety. [57]

#### **Sub-score breakdown (bundle) and aggregation**

- **Approved, clinically delivered genome editing (nuclease CRISPR ex vivo) → 6**
- Support: regulatory product evidence and authorisations in multiple regions. [55]
- **Base editing (precision single-base repair; emerging in vivo use) → 5**
- Support: IND-enabling ex vivo HSPC correction up to 70% with minimal off-target/bystander edits; published patient-specific in vivo base-editing case under regulatory approval. [51]
- **Prime editing (versatile small edits; delivery still a key constraint) → 4**
- Support: high-efficiency in vivo mouse editing with dual AAV (up to 42% cortex, 46% liver); transient prime editor RNP delivery via engineered VLPs; but still largely preclinical. [58]
- **Gene-sized insertion / large payload writing (PASTE, CAST/evoCAST) → 4**
- Support: PASTE (~36 kb insertion across multiple human contexts) and evoCAST (~10–30% integration of kb cargoes across 14 loci) represent strong lab-to-prototype progress; still early for in vivo therapeutic deployment. [11]

- **Gene switching via epigenome editing (durable, reversible control without sequence rewrite) → 4**
- Support: durable in vivo silencing nearly 1 year after transient delivery; NHP reductions in PCSK9 (~90%) and LDL-C (~70%) with reversibility demonstration in mice; still preclinical. [6]
- **Measurement/QC/standards infrastructure (off-target discovery + inter-lab standards) → 4–5**
- Support: editor-specific, sensitive off-target profiling method (CHANGE-seq-BE) and active standards/ILS programmes; full standard adoption and universal qualification pathways still evolving. [59]

**Aggregation to one score:** Because these subthreads share a common value proposition (“more predictable, auditable, programmable edits”) but are at different translation stages, the overall ART score is best represented as an **average weighted by therapeutic maturity signals**, yielding **5** (with one sub-area already at 6, several at 4–5, and a clear metrology/regulatory ramp). [60]

## ART 09.068 mRNA Therapies & Vaccines

### ART extraction

### Primary capability the ART claims

- A reconfigurable “software-defined” biopharmaceutical platform where changing the **mRNA sequence** changes the therapeutic or vaccine antigen/protein, while much of the synthesis, formulation, and QC workflow remains reusable across products. [1]
- Rapid design-to-manufacture iteration (including strain/variant updates) by leveraging platform manufacturing and prior clinical/quality knowledge, rather than rebuilding a bespoke process for each new target. [2]
- In vivo delivery of short-lived mRNA “instructions” via engineered carriers (predominantly lipid nanoparticles), enabling temporary protein expression in specific tissues for prophylaxis (vaccines) and therapy (e.g., protein replacement; immune priming; gene-editing payload delivery). [3]

### Key sub-components and variants

- **mRNA design layer:** sequence/UTRs/capping/poly(A) and nucleoside modification choices; for personalised products, per-patient sequence generation and tracking. [4]
- **Delivery carriers:** lipid nanoparticles (LNPs) and “tunable” LNP chemistries (ionisable/degradable lipids; supplementary components); alternative delivery systems (e.g., polymers) are explicitly contemplated by regulators. [5]
- **Targeting / biodistribution control:** organ- or tissue-selective LNP design approaches (e.g., selective organ targeting; formulation rules that bias delivery beyond the liver). [6]
- **Form-factor and stability innovations:** lyophilised mRNA-LNP powders; prefilled syringes; microneedle patch formats aimed at reducing cold-chain dependence and simplifying administration. [7]
- **Manufacturing & QC infrastructure:** scalable mixing/formulation methods (microfluidic mixing modules, scale-up workflows); validated analytics for identity, integrity, potency, encapsulation, lipid composition, and nanoparticles size/PDI; development of reference materials to standardise measurement. [8]
- **Safety constraints & monitoring:** innate immune activation / inflammatory adverse events (notably rare myocarditis/pericarditis signals for COVID-19 mRNA vaccines; infusion-related reactions in IV LNP-mRNA therapeutics), requiring surveillance, risk management, and in some cases premedication. [9]

### Maturity indicators that would count as strong evidence

- **Licensed / approved products** in multiple indications (not only pandemic COVID-19) and in multiple jurisdictions, with clear labelled storage/packaging and validated CMC. [10]
- **Large-scale lot/batch release and consistency** measured by regulators or national control labs across many batches, with trending and comparability evidence. [11]
- **Peer-reviewed human clinical efficacy/safety results** for non-vaccine therapeutics (protein replacement, personalised cancer vaccines, in vivo gene editing using LNP-delivered mRNA components). [12]
- **Delivery targeting improvements** demonstrated with reproducible in vivo data (e.g., organ-selective delivery, reduced off-target uptake, improved therapeutic index). [13]

- **Operational advances reducing deployment friction:** thermostability beyond ultra-cold storage; alternative administration formats (patches); scalable manufacturing equipment and workflows; emerging standards and reference materials. [14]

#### Evidence (10–20 recent, reliable sources)

##### 1) **Efficacy and Safety of an mRNA-Based RSV PreF Vaccine in Older Adults**

Authors/organisation: Eleanor Wilson[15] et al.

Venue/type: The New England Journal of Medicine[16] (peer-reviewed phase 2–3 randomised trial; PubMed record)

Publication date: Dec 2023

Link: <https://pubmed.ncbi.nlm.nih.gov/38091530/>

Concrete progress: Vaccine efficacy reported as 83.7% against RSV-associated LRTD with  $\geq 2$  signs/symptoms and 82.4% with  $\geq 3$  signs/symptoms in adults  $\geq 60$ , demonstrating a non-COVID mRNA vaccine can reach late-stage efficacy endpoints in a large trial. [17]

##### 2) **Summary Basis for Regulatory Action — MRESVIA (Respiratory Syncytial Virus Vaccine)**

Authors/organisation: U.S. Food and Drug Administration[18]

Venue/type: Regulatory approval dossier (CMC + clinical summary)

Publication date: May 2024

Link: <https://www.fda.gov/media/179634/download>

Concrete progress: Describes an approved mRNA-LNP RSV vaccine with defined composition (50  $\mu$ g nucleoside-modified mRNA; 4-lipid LNP), **prefilled syringe** presentations, and labelled storage/expiry (including allowance for limited 2–8°C storage), evidencing mature product packaging and regulated cold-chain parameters. [19]

##### 3) **mRESVIA EPAR Public Assessment Report**

Authors/organisation: European Medicines Agency[20]

Venue/type: Regulatory assessment report (quality + nonclinical + clinical)

Publication date: 2024 (report year on dossier; month not reliably extractable from captured lines)

Link: [https://www.ema.europa.eu/en/documents/assessment-report/mresvia-epar-public-assessment-report\\_en.pdf](https://www.ema.europa.eu/en/documents/assessment-report/mresvia-epar-public-assessment-report_en.pdf)

Concrete progress: Documents manufacturing-site GMP compliance, identifies the 4-lipid LNP composition, and discusses process validation/PPQ lots and lot comparability (including reliance on platform learnings from an existing mRNA product where LNP composition and equipment are shared), supporting “platform reuse” maturity claims. [21]

##### 4) **EUA Decision Memorandum for Moderna COVID-19 Vaccine (2024–2025 Formula)**

Authors/organisation: ModernaTX, Inc.[22] / U.S. Food and Drug Administration[18]

Venue/type: Regulatory decision memorandum (EUA amendment; includes CMC and safety rationale)

Publication date: Aug 2024

Link: <https://www.fda.gov/media/167306/download>

Concrete progress: Explicitly bases authorisation of an updated strain formulation on prior clinical and postmarketing evidence “manufactured using the same process,” and notes CMC information for a **pre-filled syringe presentation**, illustrating how rapid updates can leverage platform manufacturing and accumulated safety data. [23]

### 5) **Quality assurance and control — test results of COVID-19 mRNA vaccines from Pfizer and Moderna**

Authors/organisation: Therapeutic Goods Administration[24]

Venue/type: National control laboratory / regulator report on batch release testing

Publication date: Aug 2025

Link: <https://www.tga.gov.au/resources/publication/tga-laboratory-testing-reports/quality-assurance-and-control-test-results-covid-19-mrna-vaccines-pfizer-and-moderna>

Concrete progress: Reports testing of 167 batches supplied in Australia (RNA identity/content/integrity/potency; encapsulation; lipid identity/content; LNP size/PDI; endotoxin) with all batches passing specifications and showing high comparability; this is direct evidence of industrial-scale QC and consistent manufacture. [25]

### 6) **Progress reports — Strengthening local production of medicines and health technologies (includes mRNA technology transfer hub update)**

Authors/organisation: World Health Organization[26]

Venue/type: Authoritative multilateral programme report (World Health Assembly document)

Publication date: May 2025

Link: [https://apps.who.int/gb/ebwha/pdf\\_files/WHA78/A78\\_34Rev1-en.pdf](https://apps.who.int/gb/ebwha/pdf_files/WHA78/A78_34Rev1-en.pdf)

Concrete progress: States that the mRNA technology transfer hub developed an effective COVID-19 mRNA construct and is transferring it to 15 partners across six WHO regions, evidencing ecosystem-building for distributed manufacturing capacity (a precursor to platform scaling beyond a few originator firms). [27]

### 7) **Individualised neoantigen therapy mRNA-4157 (V940) plus pembrolizumab versus pembrolizumab monotherapy in resected melanoma (KEYNOTE-942)**

Authors/organisation: Jeffrey S Weber[28] et al.

Venue/type: The Lancet[29] (peer-reviewed randomised phase 2b study)

Publication date: Feb 2024

Link:

<https://www.sciencedirect.com/science/article/abs/pii/S0140673623022687>

Concrete progress: Reports improved recurrence-free survival signals for a **personalised mRNA neoantigen** product combined with checkpoint blockade (HR for recurrence/death 0.561; 18-month RFS 79% vs 62%), demonstrating feasibility and clinical traction of per-patient mRNA “recipes” beyond prophylactic vaccines. [30]

### 8) **Interim analyses of a first-in-human phase 1/2 mRNA trial for propionic acidemia**

Authors/organisation: Dwight Koeberl[31] et al.

Venue/type: Nature[32] (peer-reviewed first-in-human therapeutic trial)

Publication date: Apr 2024

Link: <https://www.nature.com/articles/s41586-024-07266-7>

Concrete progress: In a first-in-human study of IV LNP-delivered dual mRNA (PCCA/PCCB), 346 doses over 15.69 person-years with no dose-limiting toxicities were reported, alongside a preliminary 70% reduction in risk of metabolic decompensation events in participants who had events pre-treatment—strong evidence that repeat-dose therapeutic mRNA is clinically plausible and measurable with biomarkers. [33]

### 9) **CRISPR-Based Therapy for Hereditary Angioedema (NTLA-2002)**

Authors/organisation: Intellia Therapeutics[34] (sponsor; trial paper authors include

academic and industry clinicians)

Venue/type: Peer-reviewed randomised clinical trial (via PubMed abstract record)

Publication date: 2024 (year from PubMed record; month not reliably extractable from captured lines)

Link: <https://pubmed.ncbi.nlm.nih.gov/39445704/>

Concrete progress: A single dose of an in vivo CRISPR therapy showed large reductions in hereditary angioedema monthly attack rates vs placebo ( $\approx 75$ – $77\%$  lower mean attack rate;  $40$ – $73\%$  attack-free in treated groups) with pharmacodynamic lowering of plasma kallikrein, illustrating that LNP delivery of mRNA gene-editing components can support clinically meaningful endpoints. [35]

#### 10) **Nexiguran ziclumeran gene editing in hereditary ATTR with polyneuropathy**

Authors/organisation: Julian D Gillmore[36] et al.; funded by Intellia Therapeutics[34] and Regeneron Pharmaceuticals[37]

Venue/type: Peer-reviewed clinical trial (via PubMed record)

Publication date: Sep 2025 (Epub)

Link: <https://pubmed.ncbi.nlm.nih.gov/41002250/>

Concrete progress: Reports that a single administration was associated with rapid, deep, and durable reductions in serum transthyretin levels with follow-up functional measures reported at month 24—evidence that LNP-mediated delivery of mRNA-based gene-editing payloads is moving beyond early proof-of-principle into longer-term human outcome tracking. [38]

#### 11) **Preparation of selective organ-targeting (SORT) lipid nanoparticles (LNPs) for tissue-specific mRNA delivery**

Authors/organisation: Xu Wang[39] et al.

Venue/type: Nature Protocols[40] (peer-reviewed protocol with in vivo evaluation workflow)

Publication date: Oct 2022

Link: <https://www.nature.com/articles/s41596-022-00755-x>

Concrete progress: Provides a reproducible, modular workflow for creating organ-targeted LNPs (including microfluidic mixing options) and outlines timelines for synthesis/formulation/characterisation/in vivo evaluation, supporting plausibility of “tunable delivery” as an engineering discipline rather than bespoke art. [41]

#### 12) **Artificial intelligence-driven rational design of ionizable lipids for mRNA delivery**

Authors/organisation: Wang Wang[42] et al.

Venue/type: Nature Communications[43] (peer-reviewed; data-driven delivery-material discovery)

Publication date: Dec 2024

Link: <https://www.nature.com/articles/s41467-024-55072-6>

Concrete progress: Uses AI/virtual screening to predict key LNP properties and accelerate ionisable lipid design, directly supporting the ART’s claim that delivery carriers can become more reliable and “engineering-optimised” (potentially reducing the iteration cost of new mRNA products). [44]

#### 13) **Fast and facile synthesis of amidine-incorporated degradable lipids for versatile mRNA delivery in vivo**

Authors/organisation: Xuexiang Han[45] et al.

Venue/type: Nature Chemistry[46] (peer-reviewed experimental paper)

Publication date: Jul 2024 (Epub; accepted May 2024 in PDF)

Link: <https://mitchell-lab.seas.upenn.edu/wp-content/uploads/2024/07/s41557-024-01557-2.pdf>

Concrete progress: Demonstrates a one-pot reaction enabling ~1-hour room-temperature synthesis of a 100-lipid library and shows a lead degradable lipid that supports systemic mRNA delivery and can redirect tropism (e.g., lung/spleen targeting by formulation adjustment), addressing the ART bottleneck of precise targeting without off-target uptake.

[47]

#### 14) **Morphological Characterization of Self-Amplifying mRNA Lipid Nanoparticles**

Authors/organisation: Jacob Thelen[48] et al.; published via ACS Nano[49] with a summary hosted by National Institute of Standards and Technology[50]

Venue/type: Peer-reviewed experimental characterisation study (small-angle scattering / morphology)

Publication date: Jan 2024

Link: <https://www.nist.gov/publications/morphological-characterization-self-amplifying-mrna-lipid-nanoparticles>

Concrete progress: Reports structural morphology findings for self-amplifying mRNA LNPs (including evidence of multi-compartment “bleb” structures and modelling), strengthening plausibility for dose-sparing RNA constructs and for more rigorous structure–function design rules in mRNA delivery systems. [51]

#### 15) **A microneedle vaccine printer for thermostable COVID-19 mRNA vaccines**

Authors/organisation: Aurélien vander Straeten[52] et al.

Venue/type: Nature Biotechnology[53] (peer-reviewed prototype demonstration)

Publication date: 2024 (journal volume year; month not required for core claims captured here)

Link: <https://www.nature.com/articles/s41587-023-01774-z>

Concrete progress: Demonstrates an automated process to produce dissolvable microneedle patches containing mRNA-LNP “ink,” with reported shelf stability ≥6 months at room temperature (for a model construct) and mouse immunogenicity comparable to intramuscular dosing, supporting the ART’s anticipated move from vials toward patch-like applicators and relaxed cold-chain logistics. [54]

#### 16) **Lyophilization provides long-term stability for a lipid nanoparticle-formulated, nucleoside-modified mRNA vaccine**

Authors/organisation: Hiromi Muramatsu[55] et al.

Venue/type: Molecular Therapy[56] (peer-reviewed experimental paper)

Publication date: May 2022

Link: <https://www.sciencedirect.com/science/article/pii/S1525001622000843>

Concrete progress: Shows that mRNA-LNP vaccines can be lyophilised with physicochemical properties preserved for 12 weeks at room temperature and ≥24 weeks at 4°C, retaining in vivo expression and vaccine immunogenicity in mice—directly relevant to overcoming cold-chain constraints. [57]

#### 17) **LNP-RNA Research Grade Test Material project**

Authors/organisation: National Institute of Standards and Technology[50]

Venue/type: Authoritative standards/metrology initiative (reference material + interlab study)

Publication date: Created Jul 2024 (updated Mar 2025)

Link: <https://www.nist.gov/programs-projects/lnp-rna-research-grade-test->

## material

Concrete progress: Describes a planned LNP/RNA research-grade test material intended to standardise measurement of critical quality attributes (RNA copy number/integrity/encapsulation; LNP size/morphology; lipid purity), signalling maturation of shared metrology foundations needed for reliable, software-like scaling of mRNA products. [\[58\]](#)

### 18) Draft Guideline on the quality aspects of mRNA vaccines

Authors/organisation: European Medicines Agency[\[20\]](#) (CHMP/BWP draft for consultation)

Venue/type: Authoritative regulatory guideline (quality/CMC)

Publication date: Mar 2025

Link: [https://www.ema.europa.eu/en/documents/scientific-guideline/draft-guideline-quality-aspects-mrna-vaccines\\_en.pdf](https://www.ema.europa.eu/en/documents/scientific-guideline/draft-guideline-quality-aspects-mrna-vaccines_en.pdf)

Concrete progress: Explicitly addresses manufacturing, characterisation, specifications, and regulatory considerations for strain updates, multivalent vaccines, self-amplifying mRNA, other delivery systems, and the “platform technology/prior knowledge” approach—strong evidence that regulators are formalising repeatable pathways consistent with a platform scaling model. [\[59\]](#)

### 19) Cardiac Complications After SARS-CoV-2 Infection and mRNA COVID-19 Vaccination

Authors/organisation: Centers for Disease Control and Prevention[\[60\]](#)

Venue/type: Public health surveillance analysis (MMWR)

Publication date: Apr 2022

Link: <https://www.cdc.gov/mmwr/volumes/71/wr/mm7114e1.htm>

Concrete progress: Reports that, across ages/sexes, the risk for cardiac complications (including myocarditis/pericarditis outcomes) was higher after SARS-CoV-2 infection than after mRNA vaccination—relevant to the ART’s “rare inflammatory reactions” constraint and the benefit–risk framing that affects adoption and regulatory posture. [\[61\]](#)

### 20) Safety of COVID-19 vaccines — myocarditis and pericarditis

Authors/organisation: European Medicines Agency[\[20\]](#)

Venue/type: Regulator safety monitoring page

Publication date: Jun 2023 (page date)

Link: <https://www.ema.europa.eu/en/human-regulatory-overview/public-health-threats/coronavirus-disease-covid-19/covid-19-medicines/safety-covid-19-vaccines>

Concrete progress: States myocarditis/pericarditis have been observed in *very rare* cases with mRNA COVID vaccines and typically occur within 14 days, underscoring a persistent platform constraint (innate/inflammatory adverse reactions) that must be managed as indications expand and dosing regimens evolve. [\[62\]](#)

## Maturity score (1–7) and reasoning

### Final maturity score

6

### Evidence-to-rubric mapping

### Why the evidence rules out levels 1–5

The ART is well beyond theory, lab validation, or single-prototype PoC because multiple

mRNA-LNP vaccines have entered regulated markets with documented CMC controls, packaging, expiry dating, and formal benefit–risk assessments. [63]

It is also beyond a single-company early commercial pilot: national regulators have executed **large-scale batch release testing** across many batches with extensive analytical panels (identity, integrity, potency, encapsulation, LNP size/PDI, lipid identity/content) and report consistent compliance and comparability. [11]

In parallel, the platform is actively expanding into **non-vaccine therapeutic modalities** with peer-reviewed human evidence—ranging from personalised cancer vaccines in randomised adjuvant melanoma (phase 2b) to repeat-dose IV mRNA protein replacement in a rare disease (phase 1/2), plus in vivo gene-editing programmes that depend on delivery of mRNA components and show clinically meaningful pharmacodynamic/clinical endpoints. [64]

### Why the evidence supports level 6 specifically

Level 6 requires “products are being delivered to customers in increasing amounts; application areas are expanding; expansion of production has been clearly financed; and progress is recent.” The strongest direct indicators here are:

- **Commercial delivery with regulator-confirmed lot consistency:** the Australian regulator reports 167 tested batches supplied nationally with no adverse quality trends, a hallmark of scaled delivery and quality system maturity. [25]
- **Expansion beyond COVID into additional licensed products and formats:** the FDA’s RSV vaccine approval documentation describes an mRNA-LNP vaccine supplied as prefilled syringes with defined storage/expiry claims, and the EMA EPAR documents multi-site process qualification and platform comparability logic. [10]
- **Platform-friendly regulatory formalisation:** the EMA draft guideline explicitly addresses strain updates, multivalent constructs, self-amplifying mRNA, and a platform/prior-knowledge approach—an institutional prerequisite for high-frequency updates and broad platform pipelines. [59]
- **Scaling enablers moving into standardisation:** metrology and reference materials for LNP/RNA characterisation are being developed by NIST, supporting interoperability and repeatability across labs and manufacturers. [58]
- **Distributed capacity building underway:** the WHO reports technology transfer from the mRNA hub to multiple partners across regions—evidence of efforts to broaden manufacturing participation beyond a few originators, which aligns with platform scaling over time. [27]

Together, these meet level 6’s emphasis on real product delivery plus expansion and infrastructure maturing (QC, regulatory pathways, and manufacturing ecosystems). [65]

### What is missing to justify level 7

Level 7 implies broad, competitive delivery with *rising* customer demand and strong internally financed competition across applications. While mRNA vaccines clearly have competing products and massive historical deployment, the evidence set here does not demonstrate **rising demand across the platform as a whole**, nor does it show widespread commercial delivery of mRNA therapeutics across multiple non-vaccine indications. The clearest therapeutic programmes are still in clinical trial phases (e.g., phase 2b for personalised melanoma vaccines; phase 1/2 for protein replacement; early-to-mid stage for in vivo gene editing), and key future enablers—high-precision targeting to diverse tissues, truly cold-

chain-independent formulations at scale, and streamlined regulation for frequent personalised updates—are advancing but not yet routine commercial practice. [66] In addition, safety constraints (rare inflammatory events for vaccines; infusion-related reactions in IV LNP therapeutics) remain non-trivial and continue to shape product design and surveillance expectations, which is consistent with an expanding—but not yet fully “frictionless”—platform. [9]

### Sub-score breakdown and aggregation approach

Because this ART bundles multiple application areas whose maturities differ meaningfully, the score is an **average-weighted platform view**, not the maximum.

- **Infectious-disease mRNA vaccines (COVID + RSV): maturity ~6–7** (licensed products, regulator-tested batch consistency, strain updates leveraging platform processes). Key sources: [67]
- **mRNA therapeutics (protein replacement; personalised cancer immunotherapy): maturity ~4–5** (human trials with clinically relevant endpoints; phase 2b randomised efficacy signal in melanoma; ongoing phase 1/2 for rare-disease protein replacement). Key sources: [68]
- **In vivo gene-editing therapies using LNP-delivered mRNA components: maturity ~4–5** (randomised placebo-controlled outcomes for hereditary angioedema; longer-term follow-up emerging in ATTR-PN). Key sources: [69]
- **Next-generation delivery targeting (organ-selective / retuned LNPs): maturity ~3–4** (repeatable engineering workflow; strong preclinical tooling; still not broadly proven at commercial scale across many tissues/indications). Key sources: [70]
- **Cold-chain-relaxed presentations (lyophilised; microneedle patches): maturity ~3–4** (validated stability gains in peer-reviewed studies; promising devices; not yet the dominant commercial presentation). Key sources: [71]
- **Manufacturing/QC standardisation and regulatory scaffolding: maturity ~5–6** (formal guideline development; national lot testing; reference material initiatives). Key sources: [72]

Aggregating these into a single ART-wide score yields **6** because the platform’s core function—regulated manufacture and delivery of mRNA vaccines at scale with expanding indications—is already in mature operational reality, while several future-defining capabilities (precision targeting, stable “patch/powder-first” logistics, routine personalised updates) remain earlier-stage. [73]

## ART 09.069 Cellular Agriculture & Cultured Meat

### ART extraction

#### A) Primary capability claimed (1–3 bullets)

- Produce animal-like foods (meat-like cell mass and structured muscle/fat tissues) by expanding animal cells in controlled bioreactors instead of raising whole animals. [1]
- Produce functional food components and/or bulk protein biomass via microbial cultivation (“precision fermentation” and gas-fed single-cell protein), potentially using CO<sub>2</sub> plus H<sub>2</sub> generated by renewable-electricity-driven water electrolysis. [2]
- Deliver more consistent output (composition, safety, traceability) by industrial-style process control: dense sensing, asepsis/contamination controls, and documented batch procedures akin to biomanufacturing. [3]

#### B) Key sub-components / variants (3–7 sub-threads)

- **Cell lines & cell banking:** robust, stable lines; (ideally) high-growth, suspension-adapted, food-safe cell banks; sometimes using non-GMO immortalisation routes. [4]
- **Culture media:** serum-free / animal-component-free formulations; growth-factor cost reduction; potential media recycling and waste management. [5]
- **Bioreactor scale-up & intensified operation:** stirred-tank vs airlift vs perfusion/continuous strategies; oxygen transfer, shear, and high cell density as central constraints. [6]
- **Tissue structuring:** edible scaffolds and structured growth environments to achieve

muscle/fat-like textures; hybrid plant+cell approaches. [7]

- **Quality systems & contamination control:** aseptic operations, environmental monitoring, validated sanitation, HACCP-style plans, traceability, and in-process testing (including viral/mycoplasma risk management). [3]

- **Precision fermentation (ingredient track):** engineered microbes producing discrete proteins (e.g., dairy/egg proteins) with food regulatory pathways (GRAS in the US). [8]

- **Gas fermentation / electro-bioprocessing (biomass track):** hydrogen-oxidising bacteria or chemolithoautotrophs converting  $\text{CO}_2 + \text{H}_2$  (+  $\text{O}_2$ ) into protein-rich biomass; includes  $\text{H}_2$  handling and gas–liquid mass transfer engineering. [9]

### C) Maturity indicators for this ART (what would count as strong evidence)

- **Validated high-density processes** (e.g.,  $\geq 10^8$  cells/mL for animal cells; high protein fraction for microbial biomass) sustained over meaningful durations or multiple harvest cycles. [10]

- **Techno-economic analyses grounded in realistic bioreactor scaling** showing plausible pathways toward competitive cost of goods (COGS) and identifying dominant cost drivers (media, energy, reactors, downstream). [11]

- **Regulatory progress** (pre-market consultation closures, GRAS “no questions” letters, novel food approvals) and documented compliance frameworks (GMP/HACCP equivalents). [12]

- **Real-world market evidence** beyond tastings: inspected production facilities, repeatable batches, and early commercial sales (even if limited). [13]

- **Scale-up hardware demonstrations** (pilot-plant /  $\geq 100$  L–300 L class bioreactors for gas fermentation; larger installations and supply-chain readiness for cultivated animal cells). [14]

### Evidence (10–20 recent, reliable sources)

#### 1) Empirical economic analysis shows cost-effective continuous manufacturing of cultivated chicken using animal-free medium

Authors/organisation: Laura Pasitka et al.

Venue/type: *Nature Food* (peer-reviewed paper)

Publication date: Aug 2024 (published 21 Aug 2024)

Link: <https://www.nature.com/articles/s43016-024-01022-w>

Concrete progress: Demonstrates continuous manufacturing with tangential flow filtration sustaining multiple harvests for >20 days and achieving up to  $130 \times 10^6$  cells/mL (reported as 43% w/v yield), directly addressing manufacturability and yield—two core plausibility/maturity constraints. [15]

#### 2) Spontaneous immortalization of chicken fibroblasts generates stable, high-yield cell lines for serum-free production of cultured meat

Authors/organisation: L. Pasitka et al.

Venue/type: *Nature Food* (peer-reviewed paper)

Publication date: 2023 (vol. 4, pp. 35–50)

Link: <https://www.nature.com/articles/s43016-022-00658-w>

Concrete progress: Reports non-GMO (“spontaneous”) immortalised chicken fibroblast lines adapted to suspension and serum-free culture reaching  $108 \times 10^6$  cells/mL (36% w/v yield) and demonstrating adipogenesis plus a hybrid product concept where cultured fat drives flavour. [16]

#### 3) Simple and effective serum-free medium for sustained expansion of bovine satellite cells for cell cultured meat

Authors/organisation: Andrew J. Stout et al.

Venue/type: *Communications Biology* (peer-reviewed paper; open access)

Publication date: Jun 2022 (published 2 Jun 2022)

Link: <https://www.nature.com/articles/s42003-022-03423-8>

Concrete progress: Demonstrates sustained bovine satellite-cell expansion in a serum-free medium (“Beefy-9”) with ~39 h average doubling time across seven passages, supporting feasibility of serum-free growth—critical for cost, safety, and regulatory acceptability. [17]

#### 4) **Plant-based biomaterials as scaffolds for cellular agriculture**

Authors/organisation: Woo-Ju Kim et al.

Venue/type: *Future Foods* (peer-reviewed paper)

Publication date: Dec 2024 (Vol. 10, Dec 2024)

Link: <https://www.sciencedirect.com/science/article/pii/S2666833524001679>

Concrete progress: Evaluates food-grade gels (pectin/alginate and plant proteins) as edible scaffolds; reports rheological/texture performance (e.g., storage modulus >1000 Pa for selected gels) and shows 3D-printed pectin scaffolds supporting animal-cell proliferation over 5 days—direct evidence for structured-tissue enabling components. [18]

#### 5) **Exploring cost reduction strategies for serum free media development**

Authors/organisation: Jun Ping Quek et al.

Venue/type: *npj Science of Food* (peer-reviewed review; open access)

Publication date: Dec 2024 (published 21 Dec 2024)

Link: <https://www.nature.com/articles/s41538-024-00352-0>

Concrete progress: Synthesises cost drivers in serum-free media (growth factors/recombinant proteins and basal media inputs) and highlights approaches like cheaper factor production, alternative raw materials, and media recycling—evidence for a known cost bottleneck and active R&D pathways to relieve it. [19]

#### 6) **Techno-economic modeling and assessment of cultivated meat: Impact of production bioreactor scale**

Authors/organisation: Patrick G. Negulescu et al.

Venue/type: *Biotechnology and Bioengineering* (peer-reviewed paper; indexed summary)

Publication date: 2023

Link: <https://pubmed.ncbi.nlm.nih.gov/36581609/>

Concrete progress: Quantifies how scale and reactor choice drive COGS, presenting scenarios such as ~42,000 L stirred-tank (COGS ~\$35/kg), ~211,000 L stirred-tank (~\$25/kg), and ~262,000 L airlift (~\$17/kg), clarifying what “industrial scale” implies and what must improve to reach commercial viability. [20]

#### 7) **Environmental Impacts of Cultured Meat: A Cradle-to-Gate Life Cycle Assessment**

Authors/organisation: Derrick Risner et al.

Venue/type: *ACS Food Science & Technology* (peer-reviewed paper; open access via PMC)

Publication date: 2024 (eCollection listed in PubMed/PMC record)

Link: <https://pmc.ncbi.nlm.nih.gov/articles/PMC11744764/>

Concrete progress: Uses updated TEA-derived process assumptions to show near-term animal-cell-based meat could have higher environmental impacts than beef if highly refined growth media are used, strengthening the “constraints” side of the dossier (media processing and input supply chain are decisive for scaling). [21]

## 8) Food safety aspects of cell-based food

Authors/organisation: World Health Organization[22] & Food and Agriculture Organization of the United Nations[23]

Venue/type: Joint authoritative report / publication

Publication date: Mar 2023 (28 Mar 2023)

Link: <https://www.who.int/publications/i/item/9789240070943>

Concrete progress: Provides a structured hazard-and-controls view (inputs, production steps, potential biological/chemical hazards, and regulatory approaches internationally), which is directly usable for evaluating plausibility of safe scale-up and the maturity of regulatory/scientific consensus-building. [24]

## 9) Cell Culture Consultation 000002 – Scientific Memo (cultured chicken cell material)

Authors/organisation: U.S. Food and Drug Administration[25]

Venue/type: Government technical memo (regulatory scientific review)

Publication date: Nov 2022 (published 14 Nov 2022)

Link: <https://www.fda.gov/media/163261/download>

Concrete progress: Documents the agency's scientific review of a cultured chicken process (cell banking, proliferation/differentiation, hazard controls, testing, and monitoring) and states it has “no questions” regarding the firm's safety conclusion—strong maturity evidence that a specific process has passed real regulatory scrutiny. [26]

## 10) Cell-cultivated meat: an overview

Authors/organisation: Congressional Research Service[27]

Venue/type: Government report (policy + technical/regulatory synthesis)

Publication date: Sep 2023

Link: <https://www.congress.gov/crs-product/R47697>

Concrete progress: Summarises the US regulatory pathway and records milestone market events, including facility inspection grants and early restaurant sales dates for cell-cultivated chicken—evidence that the technology has moved beyond lab prototypes into regulated, customer-facing pilots. [28]

## 11) The safety of cell culture-derived food – ready for scientific evaluation

Authors/organisation: European Food Safety Authority[29]

Venue/type: Regulator publication (preparedness / risk assessment context)

Publication date: May 2023 (published 10 May 2023)

Link: <https://www.efsa.europa.eu/en/news/safety-cell-culture-derived-food-ready-scientific-evaluation>

Concrete progress: Shows EU-level regulatory preparation (scientific colloquium, risk assessment readiness) and explicitly notes that, at the time, EFSA had not yet evaluated cultured animal-cell foods—important for maturity assessment across regions and for forecasting approval timelines. [30]

## 12) How do microbial safety issues associated with meat apply to cell cultivated products?

Authors/organisation: Food Standards Agency[31] (FSA Research and Evidence; authored report entry)

Venue/type: Government research report (hazard identification + evidence gaps)

Publication date: Sep 2025 (24 Sep 2025)

Link: <https://science.food.gov.uk/article/144237-how-do-microbial-safety->

### issues-associated-with-meat-apply-to-cell-cultivated-products

Concrete progress: Assembles literature plus expert elicitation to identify where microbial hazards can enter cell-cultivated production and what monitoring/mitigations are credible (EMP, asepsis, PAT-style monitoring), reinforcing that contamination control is a first-order scaling limiter. [32]

### 13) GRAS Notice (GRN) 001145 – Agency response letter ( $\beta$ -lactoglobulin)

Authors/organisation: (US) FDA letter responding to Imagindairy Ltd. [33]

Venue/type: Government regulatory letter (GRAS “no questions”)

Publication date: Dec 2023 (digitally signed 18 Dec 2023)

Link: <https://www.fda.gov/media/187530/download>

Concrete progress: Concludes FDA has “no questions” about the firm’s GRAS conclusion for  $\beta$ -lactoglobulin produced by *Aspergillus oryzae* for use as a protein ingredient—maturity evidence that precision-fermented animal-identical proteins are entering mainstream regulatory pathways. [34]

### 14) GRAS Notice (GRN) 001249 – Agency response letter (ovalbumin preparation)

Authors/organisation: FDA letter responding to Onego Bio, Inc. [35]

Venue/type: Government regulatory letter (GRAS “no questions”)

Publication date: Sep 2025 (filed/issued September 2025)

Link: <https://www.fda.gov/media/188998/download>

Concrete progress: Provides a “no questions” response for an ovalbumin ingredient intended to replace egg/egg-white proteins in foods (with allergen-labelling considerations), demonstrating expanding regulatory acceptance of fermentation-derived functional proteins. [36]

### 15) Simultaneous biogas upgrading and single cell protein production using hydrogen oxidizing bacteria

Authors/organisation: Rui Li et al.

Venue/type: *Chemical Engineering Journal* (peer-reviewed paper)

Publication date: Jun 2024 (15 Jun 2024)

Link:

<https://www.sciencedirect.com/science/article/abs/pii/S1385894724030638>

Concrete progress: Demonstrates  $H_2$ -oxidising bacteria upgrading biogas (e.g.,  $CH_4$  from 57.09% to 98.46% in 72 h; max  $CO_2$  assimilation efficiency 27 mL/(L·h)) while producing protein-rich biomass (up to ~70.83% protein) and includes a techno-economic comparison—direct evidence for the “ $CO_2/H_2$ -fed microbial protein” track plus its engineering/safety considerations. [37]

### 16) Performance of a pilot scale pressurized deep-jet gas bioreactor for SCP production with *Cupriavidus necator* H16

Authors/organisation: Kay Domenico Novak et al.

Venue/type: *Journal of Biotechnology* (peer-reviewed paper)

Publication date: Dec 2025 (Vol. 408, Dec 2025)

Link:

<https://www.sciencedirect.com/science/article/abs/pii/S0168165625002159>

Concrete progress: Reports a custom 300-L pressurised gas bioreactor for  $CO_2$ -to-protein biomass with high gas transfer, achieving up to 90 g/L cell dry weight and ~80% crude protein,

with reported H<sub>2</sub>/O<sub>2</sub>/CO<sub>2</sub> consumption rates—strong scale-up evidence beyond benchtop for gas-fed protein systems. [38]

#### 17) **A novel electrolytic gas lift reactor for efficient microbial electrosynthesis of hydrogen-oxidizing bacterial single-cell protein from CO<sub>2</sub>**

Authors/organisation: Jinpeng Yu et al.

Venue/type: *Systems Microbiology and Biomanufacturing* (peer-reviewed paper)

Publication date: Jun 2025 (published online 18 Jun 2025)

Link: <https://journal.hep.com.cn/smab/EN/10.1007/s43393-025-00336-5>

Concrete progress: Demonstrates an integrated electrolysis + gas-lift bioreactor design for HOB-based SCP with reported maximum biomass yield of 0.20 g CDW/L/day, protein content 58.3%, and reported H<sub>2</sub> utilisation efficiency of 100%, directly supporting plausibility of tighter coupling between renewable electricity and microbial protein production. [39]

#### 18) **Global potential of sustainable single-cell protein based on variable renewable electricity**

Authors/organisation: Mahdi Fasihi et al.

Venue/type: *Nature Communications* (peer-reviewed paper; open access)

Publication date: Feb 2025 (published 10 Feb 2025)

Link: <https://www.nature.com/articles/s41467-025-56364-1>

Concrete progress: Provides a geographically resolved “power-to-protein” scale-up roadmap (industrial-scale start ~2028) and explicit cost trajectories for renewable-electricity-based protein (e.g., ~5.5–6.1 €/kg in 2028 at best sites, falling further by 2030 and beyond), supporting plausibility while also highlighting that large-scale deployment is still forward-looking. [40]

#### 19) **Singapore first to approve protein ‘made from air’**

Authors/organisation: Singapore Economic Development Board[41] (describing approval by Singapore Food Agency[42]); mentions Solar Foods[43] and its product Solein

Venue/type: Government-agency insight article (regulatory milestone description)

Publication date: Oct 2022 (27 Oct 2022)

Link: <https://www.edb.gov.sg/en/business-insights/insights/singapore-first-to-approve-protein-made-from-air.html>

Concrete progress: Reports Singapore’s approval of Solein and describes the process concept (microbes fed with H<sub>2</sub>, N<sub>2</sub>, CO<sub>2</sub>; electrolysis and direct air capture framing) and product characteristics (65–70% protein; nine essential amino acids), giving a concrete regulatory and early-market anchor point for CO<sub>2</sub>/H<sub>2</sub>-based microbial protein. [44]

### **Maturity score (1–7) and reasoning**

#### **Final maturity score: 5**

#### **Why this is at least level 5 (rules out levels 1–4)**

- Cultivated animal-cell food has progressed beyond lab proof-of-principle into **regulated production prototypes**: US pre-market consultations have been closed (“no questions” conclusions) with detailed scientific review memos describing cell banking, aseptic controls, monitoring, and hazard-management systems. [45]

- There is evidence of **early real-world commercial exposure** (highly limited, but beyond tastings): the US path included facility inspection/grants and first restaurant sales in July 2023, demonstrating functional end-to-end production and regulatory viability, consistent

with post-PoC development by multiple actors. [46]

- Technical “hard parts” are being addressed with **peer-reviewed, quantitative progress**: sustained high-density or continuous/harvestable operation (e.g.,  $130 \times 10^6$  cells/mL over >20 days via tangential flow filtration) and stable high-yield cell lines in serum-free conditions demonstrate that key manufacturing primitives are feasible, not merely conceptual. [47]

- Independent TEA/LCA work quantifies **what scale and costs would need to look like** (including 42,000–262,000 L-scale scenarios and cost drivers), which is typical of a field moving from lab prototypes into engineering-for-scale and investor/regulator-facing design constraints. [48]

### Why this is not yet level 6 (what is still missing)

- Level 6 requires products being delivered to customers “in increasing amounts” with clearly financed expansion and expanding application areas; the best public evidence accessible here supports **limited early sales and process prototypes**, but not broad, increasing-volume supply chains for cultivated meat at competitive prices. [49]

- Major bottlenecks (media cost/supply chain, energy/input intensity, and sterility/contamination risk management at industrial scale) remain decisive; the literature and safety reports emphasise that cost-effective serum-free media and reliable safety systems are still active constraints, and environmental analyses warn that near-term systems can be resource-intensive depending on media refinement. [50]

### Sub-score breakdown and aggregation

Because this ART bundles two partially different application tracks (cultivated animal tissue vs fermentation-derived ingredients/biomass) with different maturity levels, the overall score is an **average-based score**.

- **Cultivated animal cells → maturity ~5**

Evidence: Regulatory scientific review memos and US regulatory milestones plus early sales show post-PoC, production-prototype status, but limited scale. [51]

- **Precision fermentation of functional proteins → maturity ~6**

Evidence: Multiple FDA GRAS “no questions” letters for fermentation-derived animal-identical proteins (e.g.,  $\beta$ -lactoglobulin; ovalbumin) indicate products are reaching deployable ingredient status under established regulatory pathways; however, the dossier here does not itself prove large, steadily increasing commercial volumes across many customers. [52]

- **CO<sub>2</sub>/H<sub>2</sub>-fed microbial protein biomass → maturity ~4–5**

Evidence: Peer-reviewed lab-to-pilot scale demonstrations (including a 300-L pressurised CO<sub>2</sub>-to-protein bioreactor reaching 90 g/L CDW and ~80% protein) support plausibility and pilot maturity; modelling roadmaps place large-scale deployment starting later (e.g., ~2028), indicating scaling is still emerging rather than broadly commercial. [53]

**Aggregation rationale:** The three tracks share a “cellular agriculture” industrial bioprocess core, but their application pathways and scaling status differ; averaging (~5 overall) reflects (i) cultivated meat’s post-PoC status, (ii) precision fermentation’s stronger regulatory maturity, and (iii) gas-fed microbial protein’s pilot-to-early-scale trajectory. ## ART 09.070 Organoids & Tissue Engineering

### ART extraction

#### Primary capability

- Produce **repeatable, human-derived “living test articles”** (organoids to tissue patches) that better capture 3D structure and function than 2D cell layers, improving predictive power for human biology in R&D and QC.
- Enable **standardisable, automatable workflows** (plates, microfluidic chips, imaging pipelines) so constructs can be produced, monitored, compared across sites, and (in some cases) shipped/handled more like engineered products.
- Incorporate **bioengineering features** (perfusion/vascular-like microchannels, multicell co-culture, mechanical cues, embedded sensing) to reduce size/maturation limits and improve readouts.

#### Key sub-components or variants

- **Organoid production at scale** (stirred/spinning bioreactors, suspension culture, SOPs, “recipe-like” differentiation).
- **Perfusion and vascularisation strategies** (microfluidic vascular beds, synthetic microchannel networks, endothelial integration, anastomosis).
- **Organoid-on-chip / microphysiological systems (MPS)** integration (controlled flow, oxygen tension, tissue–tissue interfaces).

- **Embedded / in situ sensing and longitudinal monitoring** (TEER/barrier integrity, oxygen, pH, metabolic markers; continuous multi-day monitoring).
- **Automation + software QC** (robotic handling, high-content imaging, machine-learning classifiers to detect drift/abnormal growth).
- **Translational endpoints:** clinical correlation for patient-derived organoid drug response; tissue-engineered patches for regenerative medicine; larger organ-scale perfusion scaffolds.

#### What maturity indicators would constitute evidence

- **Repeatable lab prototypes** showing sustained function, perfusion/vascular integration, and improved maturation vs. baseline culture.
- **High-throughput/automation demonstrations** in standard formats (multiwell plates; parallelised chips; robotic liquid handling).
- **Quantified monitoring** (multi-parameter sensing, stability over weeks, reproducibility metrics, QC classifiers).
- **Standardisation/quality frameworks** from standards bodies and cross-sector consortia (terminology, reporting, fit-for-purpose qualification).
- **Regulatory traction** (official roadmaps/programmes that explicitly accept organoids/MPS as supportive evidence; validation studies; pilot qualification pathways).
- **Clinical/real-world correlation** (prospective trials demonstrating organoid drug response predicts patient outcomes; early human use of engineered tissues).

#### Evidence (10–20 recent, reliable sources)

##### 1) Creating a kidney organoid-vasculature interaction model using a novel organ-on-chip system

Authors/organisation: Amanda Bas-Cristóbal Menéndez[1] et al.

Venue/type: *Scientific Reports* (peer-reviewed experimental paper, open access)

Publication date: Nov 2022

Link: <https://www.nature.com/articles/s41598-022-24945-5>

Key result / why it matters: Demonstrates **in vitro vascularisation cues via microfluidic flow** and co-culture, including **endothelial ingrowth and lumen-like structures** inside kidney organoids—direct evidence that chip-mediated perfusion/cues can partially address the “size/maturation without perfusion” bottleneck. [2]

##### 2) Large-scale perfused tissues via synthetic 3D soft microfluidics

Authors/organisation: Sergei Grebenyuk[3] et al.

Venue/type: *Nature Communications* (peer-reviewed experimental paper, open access)

Publication date: Jan 2023

Link: <https://www.nature.com/articles/s41467-022-35619-1>

Key result / why it matters: Shows **synthetic 3D microfluidic networks** enabling **large-scale perfusion** through engineered tissues—directly supports feasibility of **microchannel-based perfusion** to push constructs beyond diffusion-limited dimensions. [4]

##### 3) Sustained in vivo perfusion of a re-endothelialized tissue engineered kidney graft in a human-scale animal model

Authors/organisation: James S. Uzarski[5] et al.

Venue/type: *Frontiers in Bioengineering and Biotechnology* (peer-reviewed experimental paper)

Publication date: Jun 2023

Link: <https://www.frontiersin.org/journals/bioengineering-and-biotechnology/articles/10.3389/fbioe.2023.1184408/full>

Key result / why it matters: Reports **human-scale scaffold perfusion performance** (e.g., quantified perfusion percentages over days), underscoring that **perfusion and endothelialisation are measurable engineering targets** for scale-up—even if full organ function remains a longer-term challenge. [6]

#### 4) Scalable production of tissue-like vascularized liver organoids from human PSCs

Authors/organisation: Sean P. Harrison[7] et al.

Venue/type: *Experimental & Molecular Medicine* (peer-reviewed experimental paper, open access)

Publication date: Sep 2023

Link: <https://www.nature.com/articles/s12276-023-01074-1>

Key result / why it matters: Demonstrates **scalable, ECM-independent production** of liver-like organoids with **vascular luminal structures** plus liver functions (e.g., metabolism, urea/coagulation-related outputs), supporting plausibility of **high-volume organoid manufacturing** with richer cellular composition than simple hepatic spheroids. [8]

#### 5) A microfluidic platform integrating functional vascularized organoids-on-chip

Authors/organisation: Clément Quintard[9] et al.

Venue/type: *Nature Communications* (peer-reviewed experimental paper, open access)

Publication date: Feb 2024

Link: <https://www.nature.com/articles/s41467-024-45710-4>

Key result / why it matters: Demonstrates a **parallelised microfluidic device** (10 channels) designed in **COC plastic suitable for mass production** and reports **controlled perfusion/anastomosis** with vascularised organoids and spheroids maintained **up to ~30 days**, directly supporting maturity of “organoid perfusion as a workflow-compatible add-on”. [10]

#### 6) From animal testing to in vitro systems: advancing standardization in microphysiological systems

Authors/organisation: Darwin R. Reyes[11] et al. (stakeholders incl. National Institute of Standards and Technology[12] and industry participants)

Venue/type: *Lab on a Chip* (peer-reviewed perspective; standards/translation-focused)

Publication date: Feb 2024

Link: <https://pubs.rsc.org/en/content/articlelanding/2024/lc/d3lc00994g>

Key result / why it matters: Summarises concrete standardisation gaps and efforts (terminology, interfaces, validation concepts) and evidences **multi-stakeholder coordination**—a key maturity signal when moving from bespoke academic prototypes to interoperable, comparable platforms. [13]

#### 7) Recommendations on fit-for-purpose criteria to establish quality management for microphysiological systems and for monitoring their reproducibility

Authors/organisation: David Pamies[14] et al.

Venue/type: *Stem Cell Reports* (peer-reviewed perspective; quality management / reproducibility)

Publication date: Apr 2024

Link: <https://pmc.ncbi.nlm.nih.gov/articles/PMC11103889/>

Key result / why it matters: Provides **fit-for-purpose quality management recommendations** for MPS/organoid-like systems (qualification, reproducibility monitoring), directly addressing the ART constraint of **batch drift/variability** and showing the field is formalising QC norms needed for scaling and cross-site adoption. [15]

#### 8) CEN-CENELEC Focus Group Organ-on-Chip Roadmap

Authors/organisation: CEN-CENELEC[16] (Focus Group on Organ-on-Chip)

Venue/type: Standards roadmap/report (authoritative standards-body publication)

Publication date: Jul 2024

Link: <https://www.cencenelec.eu/media/publication-july-2024-fg-ooc-roadmap.pdf>

Key result / why it matters: Details a Europe-wide standardisation roadmap spanning **reliability, sterilisation, material–liquid interactions, experimental design/data management, and regulatory/ethical aspects**—evidence of mature ecosystem work to make organoid/MPS platforms comparable and auditable at scale. [17]

#### 9) Development of an automated 3D high content cell screening platform for organoid phenotyping

Authors/organisation: Suleyman B. Bozal[18] et al.

Venue/type: *SLAS Discovery* (peer-reviewed experimental/methods paper, open access)

Publication date: Oct 2024

Link: <https://www.sciencedirect.com/science/article/pii/S2472555224000443>

Key result / why it matters: Demonstrates **384-well high-content organoid screening** with **robotic liquid handling** and shows image-based phenotyping can be more sensitive than basic viability assays—direct evidence that organoids can “fit existing workflows” while moving toward industrialised screening throughput. [19]

#### 10) Organ chips with integrated multifunctional sensors enable continuous metabolic monitoring at controlled oxygen levels

Authors/organisation: Zohreh Izadifar[20] et al.

Venue/type: *Biosensors and Bioelectronics* (peer-reviewed experimental paper, open access)

Publication date: Aug 2024 (epub); Dec 2024 (issue)

Link: <https://www.sciencedirect.com/science/article/pii/S0956566324006894>

Key result / why it matters: Demonstrates organ-chip devices with integrated **TEER, oxygen, and pH sensors**, operated with a **commercial culture instrument**, and reports **continuous, non-invasive monitoring up to ~23 days** in human gut/liver chip cultures—highly aligned with the ART’s “embedded sensors + longitudinal monitoring” claim. [21]

#### 11) Non-Invasive Quality Control of Organoid Cultures Using Mesofluidic CSTR Bioreactors and High-Content Imaging

Authors/organisation: Seleipiri Charles[22] et al.

Venue/type: *Advanced Materials Technologies* (peer-reviewed experimental paper; with linked preprint history)

Publication date: Aug 2024 (epub); Feb 2025 (issue)

Link: <https://pubmed.ncbi.nlm.nih.gov/40248044/>

Key result / why it matters: Integrates a **mesofluidic bioreactor** with longitudinal imaging and a **machine-learning classifier** to distinguish normal vs abnormal development, explicitly

targeting **heterogeneity/reproducibility**—a direct maturity marker for scalable “software QC” organoid pipelines. [23]

#### 12) Accelerated production of human epithelial organoids in a miniaturized spinning bioreactor

Authors/organisation: Shicheng Ye[24] et al.

Venue/type: *Cell Reports Methods* (peer-reviewed methods/experimental paper)

Publication date: Nov 2024

Link: <https://pubmed.ncbi.nlm.nih.gov/39561715/>

Key result / why it matters: Presents a miniaturised spinning bioreactor with SOP-like settings and reports faster proliferation (e.g., **multi-fold increases for liver/intestine/pancreas organoids vs static culture**) while maintaining phenotypes—strong evidence of progress on **standardisation + cost/time reduction via automation**. [25]

#### 13) Personalized Vascularized Tumor Organoid-on-a-Chip for Tumor Metastasis and Therapeutic Targeting Assessment

Authors/organisation: Yang Du[26] et al.

Venue/type: *Advanced Materials* (peer-reviewed experimental paper)

Publication date: Dec 2024 (epub); Feb 2025 (issue)

Link: <https://pubmed.ncbi.nlm.nih.gov/39726096/>

Key result / why it matters: Reports a **vascularised patient-derived tumour organoid chip** with **hierarchical microvasculature** to study tumour–vascular dynamics and drug response, evidencing feasibility of “more realistic co-culture microenvironments” beyond avascular tumoroids. [27]

#### 14) Engineered heart muscle allografts for heart repair in primates and humans

Authors/organisation: Ahmad-Fawad Jebran[28] et al.

Venue/type: *Nature* (peer-reviewed experimental translational paper, open access)

Publication date: Jan 2025

Link: <https://www.nature.com/articles/s41586-024-08463-0>

Key result / why it matters: Shows **centimetre-scale engineered heart muscle** tested in primates and humans, signalling that parts of tissue engineering have progressed beyond in vitro models into **advanced preclinical/early clinical translation**, while also highlighting the high bar for full regulatory/market maturity. [29]

#### 15) Roadmap to Reducing Animal Testing in Preclinical Safety Studies

Authors/organisation: U.S. Food and Drug Administration[30]

Venue/type: Government roadmap/report (authoritative regulatory document)

Publication date: Apr 2025

Link:

[https://www.fda.gov/files/newsroom/published/roadmap\\_to\\_reducing\\_animal\\_testing\\_in\\_preclinical\\_safety\\_studies.pdf](https://www.fda.gov/files/newsroom/published/roadmap_to_reducing_animal_testing_in_preclinical_safety_studies.pdf)

Key result / why it matters: Explicitly treats **organoids and organ-on-chip/MPS** as NAMs and states FDA intent to **welcome organoid results in IND/BLA packages as supportive data**; it also cites a **Human Liver-on-Chip** evaluated for DILI prediction and accepted into an FDA pilot programme, indicating accelerating regulatory pull for these platforms. [31]

#### 16) A feedback-driven brain organoid platform enables automated maintenance and high-resolution neural activity monitoring

Authors/organisation: Kateryna Voitiuk[32] et al.

Venue/type: *Internet of Things* (peer-reviewed experimental systems paper)

Publication date: Jul 2025 (epub); Sep 2025 (issue)

Link: <https://pubmed.ncbi.nlm.nih.gov/41522195/>

Key result / why it matters: Demonstrates an **IoT-style integrated platform** combining **microfluidics + imaging + electrophysiology**, including computer-vision feedback to correct perfusion deviations and enabling frequent neural recordings—directly aligned with “software recipes + monitored by imaging + QC/automation”. [33]

#### 17) **Gastruloids enable modeling of the earliest stages of human cardiac and hepatic vascularization**

Authors/organisation: Oscar J. Abilez[34] et al.

Venue/type: *Science* (peer-reviewed experimental paper)

Publication date: Jun 2025

Link: <https://pubmed.ncbi.nlm.nih.gov/40472086/>

Key result / why it matters: Shows micropatterned gastruloids and factor combinations that yield **branched vascular networks** in cardiac and hepatic contexts—strong plausibility evidence that **developmental programmes can be engineered** to improve organoid vascularisation (a key stated constraint). [35]

#### 18) **Patient-Derived Organoids Predict Treatment Response in Metastatic Colorectal Cancer**

Authors/organisation: Jeanine M.L. Roodhart[36] et al.

Venue/type: *Clinical Cancer Research* (peer-reviewed prospective multicentre clinical/translational study; open access via PMC)

Publication date: Dec 2025 (issue date)

Link: <https://pmc.ncbi.nlm.nih.gov/articles/PMC12666313/>

Key result / why it matters: Interim results from the OPTIC multicentre prospective study report that PDO drug sensitivity **correlates with lesion response** and demonstrates **predictive performance metrics** (e.g., PPV/NPV and AUC ranges) for chemotherapy response—direct maturity evidence that organoids can move from “plausible model” to **clinically predictive test article** in real patient workflows. [37]

#### 19) **Emulate Liver-Chip R1: A human-relevant model of the liver sinusoid using a novel, low-drug-absorbing chip**

Authors/organisation: Emulate, Inc.[38]

Venue/type: Vendor technical doc (application note with engineering specs + performance characterisation)

Publication date: Oct 2024

Link: [https://emulatebio.com/wp-content/uploads/2024/10/Emulate-Liver-Chip-R1-Application-Note\\_Characterization-and-Toxicity.pdf](https://emulatebio.com/wp-content/uploads/2024/10/Emulate-Liver-Chip-R1-Application-Note_Characterization-and-Toxicity.pdf)

Key result / why it matters: Provides concrete **engineering change + measurable specifications** (e.g., thermoplastic materials to reduce absorption, membrane pore size/thickness, flow/shear targets) and summarises hepatotoxicity-related functional readouts, illustrating that vendors are iterating toward **productised, better-controlled organ-chip consumables**—a maturity signal beyond academic one-offs. [39]

#### 20) **Upscaling: efficient generation of human lung organoids from induced pluripotent stem cells using a stirring bioreactor**

Authors/organisation: B Budeus[40] et al.

Venue/type: *Frontiers in Bioengineering and Biotechnology* (peer-reviewed experimental paper)

Publication date: Dec 2025

Link: <https://www.frontiersin.org/journals/bioengineering-and-biotechnology/articles/10.3389/fbioe.2025.1684315/full>

Key result / why it matters: Demonstrates **bioreactor-based upscaling** of hiPSC lung organoid differentiation (including design details like agitation and bubble-free aeration), supporting the plausibility of moving from artisanal organoid culture into **bioprocess-style scale-up**. [41]

### **Maturity score (1–7) and reasoning**

#### **Final maturity score: 5**

This ART (organoids + tissue engineering as “living test articles” with perfusion/sensing/automation and early translational use) best fits **Level 5: multiple well-capitalised actors are actively developing production prototypes post-PoC, with rapid progress and visible moves toward standardisation and regulatory uptake**.

#### **Evidence-to-rubric mapping**

#### **What rules out Levels 1–3 (the field is beyond “principle proven” and beyond early lab verification):**

Multiple independent peer-reviewed experimental programmes show not just theoretical feasibility but **working prototypes** for key bottlenecks: perfusion/vascularisation (kidney organoids on-chip; vascularised organoids-on-chip platforms; synthetic perfused microfluidics) and scalable production routes (spinning/bioreactor organoid expansion; high-throughput phenotyping). [42]

#### **Why Level 4 is clearly met (PoC prototypes meeting real workflow needs):**

Several systems demonstrate functions aligned with commercialisation requirements—**parallelisation, multi-week stability, sensorised monitoring, and automation**. Examples include: organoids-on-chip perfused up to ~30 days with device features framed around manufacturability (COC plastics), continuous multi-sensor monitoring up to ~23 days on a commercial instrument, and automated ML-based QC for selecting “normal” organoids during long culture. [43]

#### **Why the overall bundle reaches Level 5 (ecosystem and translation signals):**

- Standardisation and quality governance are being formalised by major standards bodies and cross-sector stakeholder groups (EU roadmap; quality management recommendations; standardisation perspective with metrology and industry participation). [44]
- Regulatory pull is explicit: the FDA’s April 2025 roadmap frames **organoids/MPS** as NAMs, indicates willingness to accept organoid results as supportive data in IND/BLA packages, and references pilot/validation activity (including an MPS example evaluated for DILI prediction and accepted into a pilot programme). [31]
- Some applications have crossed into **prospective, multicentre clinical validation** for predictive value (PDOs predicting response in metastatic colorectal cancer), showing the “living test article” concept can operate in real patient-facing pipelines—an advanced maturity indicator compared with purely academic demonstrations. [37]

### What is still missing to justify Level 6 (scaled product delivery with clear expansion economics):

While there is clear evidence of **commercial products and vendor iteration** (e.g., detailed organ-chip consumable specs and performance characterisation) and regulatory momentum, this dossier does not provide hard, auditable proof that **organoid/MPS “test article” production is being delivered to customers in increasing volumes with demonstrated economies of scale** across multiple competing products and broad routine adoption. [45]

In other words: the technology is beyond PoC and has a strong ecosystem, but **scaling evidence is uneven across sub-threads**, especially for more complex vascularised, sensorised, multicellular constructs and for regenerative tissue patches.

### Sub-scores and aggregation approach

Because this ART bundles multiple related but non-identical technologies, the maturity score is best treated as a **weighted average** (rather than pure max), with emphasis on the “living test article for R&D/QC” value proposition.

- **High-throughput organoid/MPS for drug response and screening** → ~5  
Key support: 384-well automated screening workflow (Oct 2024) and multicentre clinical correlation of PDO drug response with patient outcomes (Dec 2025). [46]
- **Perfusion/vascularisation enabling larger/more functional constructs** → ~4–5  
Key support: vascularised organoids-on-chip with perfusion and manufacturable materials (Feb 2024); kidney organoid vascularisation on-chip (Nov 2022); synthetic perfused microfluidics (Jan 2023). [47]
- **Automation + ML QC + longitudinal monitoring (the “software recipes + QC” layer)** → ~4–5  
Key support: mesofluidic bioreactor + ML classification for QC (epub Aug 2024); IoT feedback-driven organoid maintenance platform (Sep 2025). [48]
- **Therapeutic tissue patches / regenerative tissue engineering** → ~4  
Key support: engineered heart-muscle allografts tested in primates and humans (Jan 2025), indicating translation is possible but still far from commodity production and broad clinical deployment. [29]

**Aggregation to one score:** weighting the “living test article for R&D/QC” components most heavily (since that is the central claim of the ART description) yields an overall maturity at **Level 5**, with some sub-threads approaching 6 in specific niches but not enough broad production-scale evidence across the whole bundle. [49]

## ART 09.071 Synthetic Biology & Designer Microbes

### 1. ART extraction

#### Primary capability the ART claims

- Programmable “designer microbes” that convert low-value inputs into target molecules/materials in bioreactors, using modular genetic “control logic” to schedule and regulate production. [1]
- Embedded sensing-and-response: microbes detect internal/external conditions (metabolites, temperature, stress, etc.) and automatically shift metabolic fluxes or gene expression to optimise outputs. [2]
- Robustness and containment by design (auxotrophies, kill switches, multi-layer safeguards) to reduce persistence outside controlled environments and support traceability/regulatory acceptance. [3]

#### Key sub-components or variants

- **Standardised chassis and host onboarding** (bacteria/yeast; including non-model hosts) for diverse feedstocks and operating conditions. [4]
- **Dynamic regulation circuits** (quorum-sensing control, temperature-responsive logic, biosensor-triggered CRISPRi) to decouple growth and production or to perform ordered multi-stage pathway control. [5]
- **Design-build-test-learn (DBTL) automation and design representation** (standards like SBOL; metrology and reproducibility infrastructure; computational design automation) to make circuit behaviour more predictable and transferable. [6]
- **Biocontainment modules** (synthetic auxotrophy, CRISPR-based kill systems, layered/orthogonal safeguards) suitable for industry and/or applied deployments. [3]

- **Downstream processing / separations & TEA** (purification cost, ISPR approaches, minimum selling price sensitivity to feedstock and utilities). [7]
- **Commercial-scale deployments** where engineered microbes already operate at industrial scale (fuels/chemicals/enzymes), providing a maturity anchor for parts of the ART. [8]

#### What would count as maturity evidence for this ART

- Repeatable **pilot-relevant demonstrations** (e.g., litre-scale/5-L+ fermentations) showing improved titres/yields/productivity using autonomous genetic control (not manual inducer addition) and stable behaviour across runs. [5]
- **Validated robustness/containment**: multi-layer safeguards with demonstrated evolutionary stability (e.g., >100 generations under permissive conditions) and clear performance in relevant chassis. [9]
- **Standardisation + metrology adoption** (interlab-compatible measurement practices; machine-readable design standards; shared protocols/datasets) that reduce “one-lab-only” effects. [10]
- **Evidence of scaling and industry pull**: funded consortia with explicit scale-up/DBTL objectives, regulatory filings showing commercial operation, and regulatory dossiers describing containment/quality controls. [11]
- **Economics evidence**: TEA/ISPR showing that separation and feedstock/utility costs can plausibly meet target MSP ranges under realistic scenarios. [12]

#### Evidence (10–20 recent, reliable sources)

#### 2. Evidence (10–20 recent, reliable sources)

##### Sources (all within the strict 4-year window: Feb 2022–Feb 2026)

##### 1) Meeting Measurement Precision Requirements for Effective Engineering of Genetic Regulatory Networks

Authors/Org: Jacob Beal[13] et al.

Venue/type: ACS Synthetic Biology[14] (peer-reviewed paper)

Publication date: **Feb 2022** (web publication date)

Link: <https://pubs.acs.org/doi/abs/10.1021/acssynbio.1c00488>

Annotation: Derives an “engineering error inequality” linking model accuracy and measurement precision, and recommends ~**1.5-fold** target standard deviation; shows via an interlaboratory flow cytometry study that such requirements can be met with matched channels and independent calibration—supporting plausibility of predictable, modular genetic control. [15]

##### 2) Synthetic biology open language (SBOL) version 3.1.0

Authors/Org: Lukas Buecherl[16] et al.

Venue/type: Journal of Integrative Bioinformatics[17] (peer-reviewed standards paper)

Publication date: **Mar 2023** (published online)

Link: <https://www.degruyter.com/document/doi/10.1515/jib-2022-0058/pdf>

Annotation: Updates SBOL with clarified semantics and validation rules, strengthening machine-readable representation of genetic designs—directly aligned with the ART’s “software-defined” circuits and interoperable workflows. [18]

### 3) **Protocols, datasets, and software for engineering biology**

Authors/Org: National Institute of Standards and Technology[19] (programme page)

Venue/type: Government lab programme resources / protocols

Publication date: **Jun 2024**

Link: <https://www.nist.gov/programs-projects/protocols-datasets-and-software-engineering-biology>

Annotation: Curates reproducibility-focused automation protocols and datasets (including automated culture/measurement and DNA template preparation), indicating institutional investment in standardised measurement and repeatable DBTL pipelines—critical to scaling programmable microbes. [20]

### 4) **2023 Project Peer Review Report: Agile BioFoundry Consortium (ABF section)**

Authors/Org: U.S. Department of Energy Bioenergy Technologies Office[21] (authoritative programme report section)

Venue/type: Government programme peer-review report (report/PDF)

Publication date: **Apr 2024** (posted)

Link: [https://www.energy.gov/sites/default/files/2024-04/beto-2023-peer-review-report\\_03-agile-biofoundry.pdf](https://www.energy.gov/sites/default/files/2024-04/beto-2023-peer-review-report_03-agile-biofoundry.pdf)

Annotation: Documents major, multi-lab DBTL/scale-up infrastructure with ~**\$86.9M** DOE investment reviewed, and frames ABF's mission and industrial engagement (including targets such as reducing time to scale-up)—evidence of well-capitalised actors pushing beyond lab PoC. [22]

### 5) **A pathway independent multi-modular ordered control system based on thermosensors and CRISPRi improves bioproduction in *Bacillus subtilis***

Authors/Org: Wenwen Yu[23] et al.

Venue/type: Nucleic Acids Research[24] (peer-reviewed experimental paper)

Publication date: **Jun 2022** (24 Jun 2022)

Link: <https://academic.oup.com/nar/article/50/11/6587/6603658>

Annotation: Demonstrates programmable temperature-responsive circuits plus CRISPRi logic for ordered metabolic control; reports **2'-fucosyllactose 28.2 g/L in a 5-L bioreactor** (and 5.16× improvement in shake flask), providing strong plausibility evidence for “software-like” production timing in existing fermenters. [25]

### 6) **A quorum sensing-controlled type I CRISPRi toolkit for dynamically regulating metabolic flux**

Authors/Org: Han Zheng[26] et al.

Venue/type: Nucleic Acids Research (peer-reviewed experimental paper)

Publication date: **Jul 2025** (published 19 Jul 2025)

Link: <https://academic.oup.com/nar/article/53/14/gkaf693/8208113>

Annotation: Builds an inducer-free QS→CRISPRi dynamic regulator; reports **14.97 g/L D-pantothenic acid in 5-L fed-batch** and **2.49× riboflavin** improvement—pilot-relevant evidence that autonomous logic can materially improve titres without costly external inducers. [27]

### 7) **Engineering genetic circuits for dynamic control of central metabolism**

Authors/Org: Yusong Zou[28] et al.

Venue/type: Metabolic Engineering[29] (peer-reviewed experimental paper)

Publication date: **Sep 2025**

Link:

<https://www.sciencedirect.com/science/article/abs/pii/S109671762500093X>

Annotation: Establishes a pyruvate-responsive biosensor (PdhR) and uses it for dynamic flux control; reports **trehalose 3.72 g/L (2.33×)** and **4-hydroxycoumarin 491.5 mg/L (1.63×)**, illustrating generalisable central-metabolism triggers for programmable cell factories. [30]

#### 8) **Computational design of allulose-responsive biosensor toolbox for auto-inducible protein expression and CRISPRi mediated dynamic metabolic regulation**

Authors/Org: Qianzhen Dong[31] et al.

Venue/type: Nature Communications (peer-reviewed experimental paper)

Publication date: **Dec 2025** (published 22 Dec 2025)

Link: <https://www.nature.com/articles/s41467-025-67669-6>

Annotation: Structure-guided design yields an allulose-responsive sensor with **EC50 reduced from 16 mM to 0.8 mM** and wide detection range; demonstrates auto-inducible expression and allulose-triggered CRISPRi dynamic regulation, supporting the ART's "sense→actuate" logic with quantitative performance. [32]

#### 9) **Precision engineering of biological function with large-scale measurements and machine learning**

Authors/Org: Drew S. Tack[33] et al.

Venue/type: PLOS ONE[34] (peer-reviewed experimental paper)

Publication date: **Mar 2023** (published 29 Mar 2023)

Link:

<https://journals.plos.org/plosone/article?id=10.1371/journal.pone.0283548>

Annotation: Demonstrates "precision engineering" of genetic sensors using large-scale genotype–phenotype data and ML, including multi-objective tuning of sensor EC50 and output—evidence that genetic "control logic" can become more predictable and designable. [35]

#### 10) **Energy Aware Technology Mapping of Genetic Logic Circuits**

Authors/Org: Erik Kubaczka[36] et al.

Venue/type: ACS Synthetic Biology (peer-reviewed paper; design automation)

Publication date: **Oct 2024**

Link: <https://garcialab.berkeley.edu/publications/Kubaczka2024.pdf>

Annotation: Introduces automated mapping of Boolean genetic circuits with energy/efficiency objectives; reports **~37.2% average energy-efficiency improvement** versus function-optimised variants, a concrete step toward scalable software-defined genetic circuit design under resource constraints. [37]

#### 11) **A robust yeast biocontainment system with two-layered regulation switch dependent on unnatural amino acid**

Authors/Org: T. Chang[38] et al.

Venue/type: Nature Communications[39] (peer-reviewed experimental paper)

Publication date: **Oct 2023** (published 14 Oct 2023)

Link: <https://www.nature.com/articles/s41467-023-42358-4>

Annotation: Demonstrates synthetic auxotrophy in budding yeast dependent on an unnatural amino acid as a robust containment strategy—direct evidence that "engineered dependencies" can be implemented in an industrially relevant chassis. [40]

### 12) **GenoMine: a CRISPR-Cas9-based kill switch for biocontainment of *Pseudomonas putida***

Authors/Org: Enrique Asin-Garcia[41] et al.

Venue/type: Frontiers in Bioengineering and Biotechnology[42] (peer-reviewed experimental paper)

Publication date: **Sep 2024** (published 16 Sep 2024)

Link: <https://www.frontiersin.org/journals/bioengineering-and-biotechnology/articles/10.3389/fbioe.2024.1426107/full>

Annotation: Presents a CRISPR-Cas9 kill switch targeting repetitive genomic elements in the biotechnological workhorse *P. putida*, supporting plausibility of programmable safeguards beyond lab strains. [43]

### 13) **A multilayered biocontainment system for laboratory and probiotic yeast**

Authors/Org: Carla Maneira[44] et al.

Venue/type: Metabolic Engineering (peer-reviewed experimental paper)

Publication date: **Sep 2025**

Link: <https://www.sciencedirect.com/science/article/pii/S1096717625000953>

Annotation: Builds single-input safeguards (synthetic auxotrophy and CRISPR-based kill switch) and combines them into an orthogonal two-input system; reports circuits stable for **>100 generations** and aligned to NIH guideline expectations—important maturity step for containment engineering. [45]

### 14) **Genetic “expiry-date” circuits control lifespan of synthetic scavenger bacteria for safe bioremediation**

Authors/Org: Kha Mong Tran[46] et al.

Venue/type: Nucleic Acids Research (peer-reviewed experimental paper)

Publication date: **Jul 2025** (published 24 Jul 2025)

Link: <https://academic.oup.com/nar/article/53/14/gkaf703/8211935>

Annotation: Implements genetic “expiry-date” circuits to limit lifespan of engineered bacteria for safer applications, demonstrating timed self-limitation logic relevant to both containment and field-facing variants of the ART. [47]

### 15) **A bumpy road ahead for genetic biocontainment**

Authors/Org: Dalton R. George[48] et al.

Venue/type: Nature Communications (peer-reviewed commentary)

Publication date: **Jan 2024** (20 Jan 2024)

Link: <https://www.nature.com/articles/s41467-023-44531-1>

Annotation: Argues that few real-world biotech products currently include intrinsic biocontainment, highlighting testing capacity and regulatory uncertainty—evidence that containment remains a maturity limiter for “deployable” designer microbes. [49]

### 16) **GRAS Notice 1104: Non-animal egg white protein produced by *Komagataella phaffii***

Authors/Org: U.S. Food and Drug Administration[50] (regulatory dossier; submitter: Clara Foods / EVERY)

Venue/type: Regulatory technical dossier (manufacture, monitoring, purification)

Publication date: **Sep 2022** (received stamp SEP 12 2022)

Link: <https://www.fda.gov/media/170789/download>

Annotation: Describes an engineered-yeast precision fermentation process with defined unit operations (fermentation → cell separation → purification → drying) and in-process checks

aimed at contamination control and specifications—direct maturity evidence for regulatory traceability and QA/QC workflows around engineered microbes. [51]

**17) GRAS Notice 1139: Transglutaminase enzyme produced by genetically modified *Bacillus licheniformis***

Authors/Org: U.S. FDA (regulatory dossier; submitter: Novozymes)

Venue/type: Regulatory technical dossier (identity, strain lineage, safety studies)

Publication date: **Apr 2023** (date of receipt: Apr 3 2023)

Link: <https://www.fda.gov/media/178428/download>

Annotation: Specifies a production organism and construct details (GM *Bacillus* carrying a *Streptomyces* transglutaminase gene) and documents safety-study expectations—concrete evidence that engineered microbial “factories” and their products already traverse formal regulatory pathways. [52]

**18) Form 10-Q (quarter ended 31 Mar 2025): LanzaTech Global, Inc.**

Authors/Org: LanzaTech Global, Inc. [53] filing with U.S. Securities and Exchange Commission [54]

Venue/type: Public company regulatory filing (commercial operations evidence)

Publication date: **2025** (reporting quarter ended Mar 2025)

Link:

<https://www.sec.gov/Archives/edgar/data/1843724/000162828025026381/lnza-20250331.htm>

Annotation: States that as of **31 Mar 2025** the company’s technology was operated by licensees at **multiple commercial-scale ethanol plants** (including four in China and one in Belgium, with one commissioning in India), anchoring that engineered-microbe industrial bioprocessing is already commercially deployed at scale. [55]

**19) Techno-economic analysis as a valuable tool for the selection of high-potential extractive fermentation approaches for large-scale prodigiosin production**

Authors/Org: Ulises Andres Salas-Villalobos [56] et al.

Venue/type: Chemical Engineering Journal [57] (peer-reviewed TEA; open access)

Publication date: **Feb 2024** (Vol 481, 1 Feb 2024)

Link: <https://www.sciencedirect.com/science/article/pii/S1385894723070110>

Annotation: Shows downstream/separation and process mode materially change economics: continuous extractive operation decreased costs **4.73×** vs batch and includes a concrete scale design point (reactor volume/flow), matching the ART’s constraint focus on DSP and separations. [58]

**20) Techno-Economic Analysis of 2,3-Butanediol Production from Sugarcane Bagasse**

Authors/Org: Siddharth Gadkari [59] et al.

Venue/type: ACS Sustainable Chemistry & Engineering (peer-reviewed TEA; open access)

Publication date: **May 2023** (published 22 May 2023)

Link: <https://pureadmin.qub.ac.uk/ws/files/554168093/gadkari-et-al-2023-techno-economic-analysis-of-2-3-butanediol-production-from-sugarcane-bagasse.pdf>

Annotation: Models an industrially scaled plant (96 MT/day bagasse) and quantifies MSP/NPV sensitivity to feedstock/utilities; reports scenario MSP spanning **~US\$1.86–3.99/kg** and provides explicit capital/operating cost tables—direct evidence that economics hinge on feedstock and separation assumptions. [60]

## Maturity score (1–7) and reasoning

### 3. Maturity score (1–7) and reasoning

Final maturity score: 5

#### Why the evidence rules out lower levels

- The ART is well beyond “principle only” (levels 1–2) because multiple peer-reviewed experiments show programmable genetic control systems that improve titres/yields, including in **5-L bioreactors/fed-batch** at tens of g/L for some products—this is beyond basic lab principle verification. [\[61\]](#)
- The ART is beyond “single lab prototype” (level 3) because several independent, recent demonstrations cover different control modalities (thermosensors+CRISPRi, QS→CRISPRi, metabolite biosensors) and show quantified performance gains on relevant chassis. [\[5\]](#)
- There is clear evidence of **serious scale-up ecosystem and funding** (e.g., ABF peer review with large DOE investment) and of regulatory-ready manufacturing descriptions (FDA GRAS dossiers), indicating the field is operating in a post-PoC landscape rather than exploratory science. [\[62\]](#)

#### Why the evidence does not justify the next higher level

- Level 6 would require that the **core ART functionality**—a broadly standardised, reconfigurable “software-defined” platform for multiple outputs with predictable behaviour across chassis and batches—be routinely delivered and scaled as products/services, not merely demonstrated project-by-project. Current evidence shows strong **domain-specific** successes and real commercial deployments for certain engineered-microbe processes, but not a universally plug-and-play programmable microbe platform. [\[63\]](#)
- Containment remains a gating factor for broader deployment outside closed systems; even commentary in a leading journal notes limited real-world incorporation of intrinsic biocontainment and points to regulatory/testing uncertainties. [\[64\]](#)
- TEA and extractive-fermentation studies underscore that downstream processing and feedstock/utility costs remain dominant determinants of viability (i.e., scaling is not “solved by circuits alone”), which is consistent with the ART’s stated constraints and suggests remaining barriers to generalised, low-capex distributed deployment. [\[12\]](#)

#### Sub-score breakdown and aggregation

- **Industrial microbial factories already delivering outputs (enzymes/fuels/ingredients) → ~6**  
Supporting evidence: FDA GRAS dossiers documenting industrial fermentation, purification, and QA/QC (Sep 2022; Apr 2023). [\[65\]](#)  
Supporting evidence: SEC filing describing multiple commercial-scale industrial plants operating with the firm’s bioprocess technology (Mar 2025). [\[55\]](#)
- **Programmable genetic circuits for dynamic control in production-like settings → ~4–5**  
Supporting evidence: 5-L bioreactor/fed-batch PoCs with large titre gains using thermosensor/CRISPRi and QS→CRISPRi dynamic regulation. [\[66\]](#)  
Supporting evidence: Metabolite-responsive biosensors improving titres and demonstrating generalisable central-metabolism triggers. [\[67\]](#)

- **Biocontainment modules suitable for industrial organisms → ~4**

Supporting evidence: Robust yeast containment via synthetic auxotrophy and layered safeguards, including stability claims (>100 generations) in a peer-reviewed engineering journal. [68]

Limiter evidence: commentary emphasising the gap between lab proposals and real-world deployment for intrinsic containment. [64]

- **Standardisation, metrology, and DBTL automation to make “genetic control logic” modular/predictable → ~4–5**

Supporting evidence: Interlab measurement precision guidance (Feb 2022), SBOL 3.1 standardisation (Mar 2023), NIST protocols for reproducibility/automation (Jun 2024), and design automation advances that quantify resource trade-offs (Oct 2024). [69]

Supporting evidence: Government scale-up consortia emphasising DBTL infrastructure and industrial engagement. [22]

**Aggregation method:** average across sub-components (because the ART’s value proposition depends on integration of production microbes + programmable control + containment + scalable/standardised workflows). Using approximate sub-scores (6, 4.5, 4, 4.5) gives ~4.75 → **rounded to 5** as the single ART maturity score. [70]

## ART 09.072 Microbiome Engineering

### ART extraction

#### Primary capability claimed

- Practical **steering of complex microbial ecosystems** (human gut, soil, water, engineered bioprocesses) by *measuring* community state, *predicting* responses, and *actuating* targeted perturbations—rather than treating the ecosystem as an opaque “black box”. [1]
- A **configurable “toolkit”** that makes microbial dynamics measurable and actionable for non-specialists (e.g., through rapid sequencing, reference standards, dashboards, and validated intervention form factors like capsules/coatings/sprays). [2]

#### Key sub-components and variants

- **Measurement / profiling:** shotgun/long-read metagenomics; absolute quantification; rapid sample-to-result workflows; reference materials; standards for data processing and reporting; time-series monitoring dashboards. [3]
- **Design / prediction:** metabolic/ecological modelling pipelines and data-driven methods that connect composition  $\leftrightarrow$  function  $\leftrightarrow$  intervention (e.g., modelling metabolic interactions to identify “keystone” species). [4]
- **Actuation (non-genetic):** selective antimicrobials, phage cocktails, nutrient/prebiotic “nudges”, community reseedling with defined consortia or microbiota-derived products. [5]
- **Actuation (genetic / precision):** in situ bacterial editing, engineered phage delivering CRISPR payloads, engineered living therapeutics with control circuits. [6]
- **Delivery & operations:** stable formulations, dosing regimens, shelf life, manufacturing controls (CMC), and deployment logistics across clinical, agricultural, and environmental settings. [7]

- **Safety & governance:** biocontainment systems, strategies to block gene transfer and environmental escape, plus regulatory/standardisation frameworks. [8]

#### Maturity indicators that would constitute strong evidence

- **Regulated products** (or late-stage clinical pipelines) demonstrating repeatable clinical outcomes and manufacturable dosing forms. [9]
- **Large multi-site trials / real-world cohorts** (hundreds of participants) showing safety and durable outcomes across heterogeneous populations. [10]
- **Field trials** in agriculture/environment showing quantified functional benefit (e.g., kg N/ha delivered; pollutant degradation), plus “commercial-grade” formulations. [11]
- **Standardisation & QA infrastructure:** ISO technical specifications, government/consortium standardisation reports, and validated reference materials supporting workflow benchmarking. [12]
- **Rapid monitoring + feedback loops** demonstrated with real-time analytics and dashboards (moving from “sample once” to “operate continuously”). [13]
- **Biosafety controls** validated in vivo/ex situ (e.g., preventing escape, blocking horizontal transfer, or timed self-destruction). [14]

#### Evidence (10–20 recent, reliable sources)

##### Portfolio coverage

The dossier below intentionally spans (i) **gut microbiome actuation** (regulated products + defined consortia trials), (ii) **environmental/soil actuation** (field and bioremediation demonstrations), and (iii) enabling infrastructure for a “toolkit” approach—**measurement, standards, benchmarking, and monitoring**—plus (iv) **precision/engineered interventions and biocontainment** for safety and governance. [15]

#### 1) ISO/TS 24420:2023 Biotechnology — Massively parallel DNA sequencing — General requirements for data processing of shotgun metagenomic sequences

Authors/Org: International Organization for Standardization[16] (ISO)

Venue/type: Standards body technical specification

Publication date: May 2023 (Edition 1, 2023-05)

Link: <https://www.iso.org/standard/78741.html>

Key evidence: Establishes requirements and guidance for **QC, metadata, storage and interoperability** for shotgun metagenomic processing across host-associated and environmental metagenomes—an indicator that microbiome measurement pipelines are moving from artisanal practice toward standardised, auditable workflows. [17]

#### 2) Challenges and current actions to address standardisation of the human gut microbiome analysis (JRC139121 / EUR 40029)

Authors/Org: Brigitte Toussaint[18]; European Commission Joint Research Centre[19]

Venue/type: Authoritative government lab/report (EU)

Publication date: September 2024

Link:

[https://www.researchgate.net/publication/384596584\\_Challenges\\_and\\_current\\_actions\\_to\\_address\\_standardisation\\_of\\_the\\_human\\_gut\\_microbiome\\_analysis](https://www.researchgate.net/publication/384596584_Challenges_and_current_actions_to_address_standardisation_of_the_human_gut_microbiome_analysis)

Key evidence: Documents that gut microbiome analysis is already “on the market” but highlights key maturity blockers—**high inter-individual variability, reference material**

**scarcity, and incomplete standardisation**—which directly maps to the ART’s stated constraints and validation burden. [20]

### 3) **Analytical assessment of metagenomic workflows for pathogen detection with NIST RM 8376 and two sample matrices**

Authors/Org: Jason G. Kralj[21] et al.; (uses National Institute of Standards and Technology[22] RM 8376)

Venue/type: Peer-reviewed paper (Microbiology Spectrum)

Publication date: April 2025

Link: <https://doaj.org/article/e7ab083aaa624feabb7a0088ab64e67c>

Key evidence: Uses a NIST reference material to benchmark **analytical performance** of metagenomic workflows for pathogen detection—strong evidence that microbiome measurement/control is developing the QA/validation scaffolding needed for regulated and industrial deployments. [23]

### 4) **Rapid absolute quantification of pathogens and ARGs by nanopore sequencing**

Authors/Org: Yu Yang[24] et al.

Venue/type: Peer-reviewed paper (Science of The Total Environment)

Publication date: February 2022 (Volume 809, 25 Feb 2022)

Link:

<https://www.sciencedirect.com/science/article/abs/pii/S0048969721072661>

Key evidence: Demonstrates **near real-time (1-hour sequencing)** nanopore metagenomics with cellular spike-ins for *absolute* quantification of pathogens and antibiotic-resistance genes in wastewater—directly supporting feasible “monitoring + feedback” loops rather than slow batch testing. [25]

### 5) **Nanopore long-read-only metagenomics enables complete and high-quality genome reconstruction from mock and complex metagenomes**

Authors/Org: Lei Liu[26] et al.

Venue/type: Peer-reviewed paper (Microbiome)

Publication date: December 2022 (02.12.2022)

Link: <https://vbn.aau.dk/en/publications/nanopore-long-read-only-metagenomics-enables-complete-and-high-qu>

Key evidence: Reports a pipeline (“NanoPhase”) enabling **high-quality genome reconstruction directly from nanopore long reads** (including 275 MAGs from activated sludge with ~90% median completeness), enabling higher-resolution tracking and design of community functions. [27]

### 6) **A rapid bacterial pathogen and antimicrobial resistance diagnosis workflow using Oxford nanopore adaptive sequencing method**

Authors/Org: Hang Cheng[28] et al.

Venue/type: Peer-reviewed paper (Briefings in Bioinformatics)

Publication date: November 2022 (Volume 23, Issue 6)

Link: <https://academic.oup.com/bib/article-abstract/23/6/bbac453/6762743>

Key evidence: Shows a clinical metagenomics workflow achieving **~4.5 hours sample-to-result** and **≥8× microbial sequence yield** in 21 BALF samples—evidence that rapid microbiome/pathogen profiling can reach clinically relevant timelines. [29]

### 7) **MMonitor for real-time monitoring of microbial communities using long reads**

Authors/Org: Timo N. Lucas[30] et al.

Venue/type: Peer-reviewed software platform paper (open access; GUI + web dashboard)

Publication date: January 2026 (collection date 26 Jan 2026)

Link: <https://pmc.ncbi.nlm.nih.gov/articles/PMC12853177/>

Key evidence: Provides an open-source **real-time analysis + visualisation dashboard** for nanopore metagenomics (taxonomic composition over time, diversity indices, correlations), explicitly targeting “monitoring” use-cases rather than offline analysis—matching the ART’s “dashboard + at-home/field tests” direction. [31]

### 8) **Engineering natural microbiomes toward enhanced bioremediation by microbiome modeling**

Authors/Org: Zhepu Ruan[32] et al.

Venue/type: Peer-reviewed paper (Nature Communications)

Publication date: June 2024 (Published 01 Jun 2024)

Link: <https://www.nature.com/articles/s41467-024-49098-z>

Key evidence: Demonstrates a top-down + bottom-up framework where herbicide + inoculation drives **convergent community succession**, and introduces **SuperCC** to model metabolic interactions; constructs a synthetic microbiome using **18 “keystone” species** for enhanced soil bioremediation—direct evidence that modelling-guided community design is becoming practical. [4]

### 9) **U.S. Food and Drug Administration[33] product page: REBYOTA (fecal microbiota, live-jslm)**

Authors/Org: FDA (product page; manufacturer listed as Ferring Pharmaceuticals Inc.[34])

Venue/type: Government regulator product record

Publication date: December 2022 (content current as of 19 Dec 2022)

Link: <https://www.fda.gov/vaccines-blood-biologics/vaccines/rebyota>

Key evidence: Confirms REBYOTA’s regulated indication (prevention of recurrent CDI after antibiotics) and provides regulatory artefacts (approval letter/SBRA), indicating microbiome-based ecosystem “reset” is beyond PoC and into licensed medical products. [35]

### 10) **Efficacy and Safety of RBX2660 in PUNCH CD3... for the Prevention of Recurrent Clostridioides difficile Infection**

Authors/Org: Sahil Khanna[36] et al.

Venue/type: Peer-reviewed Phase III RCT paper (Drugs, open access)

Publication date: October 2022 (Published 26 Oct 2022)

Link: <https://link.springer.com/article/10.1007/s40265-022-01797-x>

Key evidence: Phase III placebo-controlled trial reports Bayesian model estimates of **treatment success 70.4% vs 58.1%** (RBX2660 vs placebo) within 8 weeks, supporting plausibility and manufacturable delivery (single-dose enema) for microbiome therapeutics. [37]

### 11) **PUNCH CD3-OLS: A Phase 3 prospective observational cohort study... (REBYOTA) in adults with recurrent CDI**

Authors/Org: Paul Feuerstadt[38] et al.

Venue/type: Peer-reviewed paper (Clinical Infectious Diseases)

Publication date: January 2025 (15 Jan 2025)

Link: <https://academic.oup.com/cid/article/80/1/43/7740543>

Key evidence: Reports a large open-label cohort with **697 treated participants** and **73.8% treatment success at 8 weeks** plus **91.0% sustained response at 6 months** among successes—evidence of late-stage maturity and broad-population performance beyond tightly controlled RCTs. [10]

#### 12) **FDA news release: approval of Vowst as first orally administered fecal microbiota product for preventing recurrent CDI**

Authors/Org: FDA (approval granted to Seres Therapeutics Inc.[39] noted)

Venue/type: Government regulator press announcement

Publication date: April 2023 (26 Apr 2023)

Link: <https://www.fda.gov/news-events/press-announcements/fda-approves-first-orally-administered-fecal-microbiota-product-prevention-recurrence-clostridioides>

Key evidence: Provides controlled-trial effectiveness data (**12.4% recurrence vs 39.8% placebo** through 8 weeks) and an oral capsule regimen (4 capsules daily for 3 days), signalling a major maturity step: clinically validated, patient-friendly form factor. [40]

#### 13) **Vowst Summary Basis for Regulatory Action (SBRA) (PDF)**

Authors/Org: FDA CBER review (SBRA document)

Venue/type: Government regulator technical review (CMC + clinical summary)

Publication date: April 2023 (dated 26 Apr 2023)

Link: <https://www.fda.gov/media/168002/download>

Key evidence: Specifies product engineering details: Vowst is a spore suspension in capsules with **1×10<sup>6</sup> to 3×10<sup>7</sup> spore CFU per capsule**, dosed **4 capsules/day for 3 days**, and reports **36-month shelf life** when stored at 2°C–25°C—clear maturity signals for manufacturing, stability and deployment logistics. [41]

#### 14) **VE303, a defined bacterial consortium, for prevention of recurrent CDI: a randomised clinical trial**

Authors/Org: Thomas Louie[42] et al.

Venue/type: Peer-reviewed paper (JAMA randomised clinical trial)

Publication date: April 2023 (Published online 15 Apr 2023)

Link: <https://pmc.ncbi.nlm.nih.gov/articles/PMC10105904/>

Key evidence: Tests a **defined 8-strain consortium**; through week 8, recurrence was **13.8% (high dose)** vs **45.5% (placebo)** under an inclusive outcome definition—direct evidence that “engineered” can mean rationally defined consortia, not only donor-derived mixtures. [43]

#### 15) **In situ targeted base editing of bacteria in the mouse gut**

Authors/Org: Andreas K. Brödel[44] et al.

Venue/type: Peer-reviewed experimental paper (Nature)

Publication date: July 2024 (Published 10 Jul 2024; issue Aug 2024)

Link: <https://www.nature.com/articles/s41586-024-07681-w>

Key evidence: Demonstrates “actuation” at the gene level: a phage-derived (M13) particle delivering a base editor achieved **high in situ editing efficiency (reported ~93%)** in gut bacteria in mice—strong plausibility evidence for precision microbiome engineering, albeit preclinical. [45]

#### 16) **Engineered phage with antibacterial CRISPR-Cas selectively reduce E. coli burden in mice**

Authors/Org: Yilmaz Emre Gencay[46] et al. (affiliations include SNIPR BIOME ApS[47])

Venue/type: Peer-reviewed experimental paper (Nature Biotechnology)

Publication date: February 2024 (Epub May 2023)

Link: <https://pubmed.ncbi.nlm.nih.gov/37142704/>

Key evidence: Screens 162 wild-type phages, engineers selected phages with tail fibres + CRISPR-Cas payloads, and reports a 4-phage cocktail (SNIPR001) that is **well tolerated in mice and minipigs** and reduces gut E. coli burden; paper notes entry into clinical development—evidence bridging lab engineering to translational pipelines. [48]

#### 17) **Cas9-assisted biological containment of a genetically engineered human commensal bacterium and genetic elements**

Authors/Org: Naoki Hayashi[49] et al.

Venue/type: Peer-reviewed experimental paper (Nature Communications)

Publication date: March 2024 (Published 07 Mar 2024)

Link: <https://www.nature.com/articles/s41467-024-45893-w>

Key evidence: Implements a biocontainment architecture combining thymidine auxotrophy with a CRISPR device designed to **prevent escape via horizontal gene transfer** and **block transgene dissemination**, validated in vitro and in vivo—directly addressing the ART’s safety constraints. [50]

#### 18) **Biocontainment strategies for in vivo applications of Saccharomyces boulardii**

Authors/Org: Karl Alex Hedin[51] et al.

Venue/type: Peer-reviewed experimental paper (Frontiers in Bioengineering and Biotechnology)

Publication date: February 2023 (Published 20 Feb 2023)

Link: <https://www.frontiersin.org/journals/bioengineering-and-biotechnology/articles/10.3389/fbioe.2023.1136095/full>

Key evidence: Reports a **multi-layered biocontainment** strategy for a probiotic yeast chassis (thiamine auxotrophy; temperature sensitivity), showing restricted growth and **in-mouse tolerance** with retained peptide production—evidence that containment engineering is becoming a practical design axis, not an afterthought. [52]

#### 19) **Genetic “expiry-date” circuits control lifespan of synthetic scavenger bacteria for safe bioremediation**

Authors/Org: Kha Mong Tran[53] et al.

Venue/type: Peer-reviewed experimental paper (Nucleic Acids Research)

Publication date: July 2025 (Published 24 Jul 2025; issue Aug 2025)

Link: <https://academic.oup.com/nar/article/53/14/gkaf703/8211935>

Key evidence: Demonstrates engineered “expiry-date” kill circuits achieving an escape rate **below a cited NIH release standard ( $<10^{-10}$ )** and shows ex situ soil bioremediation where **0.1 g/kg phenol** is detoxified within **4 days** followed by bacterial self-elimination—evidence toward “single-function then fade-out” actuation demanded in the ART. [54]

#### 20) **Genetic remodeling of soil diazotrophs enables partial replacement of synthetic nitrogen fertilizer with biological nitrogen fixation in maize**

Authors/Org: Rafael Martinez-Feria[55] et al.

Venue/type: Peer-reviewed field + lab paper (Scientific Reports)

Publication date: November 2024 (Published 12 Nov 2024)

Link: <https://www.nature.com/articles/s41598-024-78243-3>

Key evidence: Uses non-transgenic gene-edited strains and reports multiple evidence layers (in vitro/in planta/field, including  $^{15}\text{N}$  tracers); inoculation with a “commercial-grade” formulation (PIVOT BIO PROVEN® 40) provides **~21 kg N/ha** to maize by VT-R1 stages on average—strong evidence that soil microbiome “nudges” can be quantified in agronomic field conditions. [11]

### Maturity score (1–7) and reasoning

#### Final maturity score

5

#### Evidence-to-rubric mapping

##### What rules out levels 1–4 (why this is beyond early research):

Clinical microbiome actuation is no longer limited to lab prototypes: multiple peer-reviewed Phase III/late-phase datasets show statistically meaningful reductions in recurrent CDI using microbiota-based therapies and defined consortia, and regulator publications document licensed/approved products and manufacturing considerations (dosing, potency ranges, shelf life). [56]

In parallel, environmental/soil microbiome interventions have crossed into field-quantified performance with isotope tracer evidence and “commercial-grade” formulations in maize systems. [11]

Measurement and operational infrastructure is maturing via standards, reference materials, and real-time monitoring tools—indicating an ecosystem forming around deployment and validation, not just discovery. [57]

##### Why the evidence does not yet justify level 6 for the ART as a whole:

Some sub-areas clearly reach “product” status (notably recurrent CDI treatments), but the ART claim is broader: a **configurable toolkit** with reliable measurement → prediction → actuation across *many* biomes and outcomes. Key blockers remain: (i) predictive design still looks context-specific (even where modelling exists), (ii) standardisation and reference materials are still described as incomplete, and (iii) for many high-value applications (metabolic/inflammatory modulation, ecosystem management at scale), evidence is still dominated by preclinical demonstrations and targeted PoCs rather than widespread scaled operations with documented adoption curves. [58]

Level 5 best matches today’s overall state: **multiple well-capitalised actors and parallel translational tracks** (FDA-regulated products; defined consortia; engineered phage approaches moving into clinical development; agricultural formulations with field evidence) are advancing quickly, but broad scaling and general-purpose predictive control remain incomplete. [59]

#### Sub-score breakdown and aggregation

- **Measurement + monitoring tooling** → ~6  
Rationale: rapid, operationally plausible sequencing workflows (including near real-time quantification) plus standards/benchmarking and monitoring dashboards. [3]
- **Design / predictive models for community steering** → ~4  
Rationale: modelling pipelines and design frameworks exist and can select/construct functional microbiomes (e.g., SuperCC + 18 keystone species), but broad

generalisation and robust closed-loop control across domains is not yet established. [4]

- **Actuation in human gut (microbiota-derived products + defined consortia)** → ~6  
Rationale: multiple late-stage clinical outcomes and regulator-documented products with defined regimens (including oral capsule delivery). [60]
- **Actuation in soil/environment (bioinoculants / synthetic microbiomes)** → ~5  
Rationale: field and tracer evidence with quantified benefit and commercial-grade formulations; still heterogeneous and context-dependent. [61]
- **Precision actuation + containment (engineered phage, in situ editing, biocontainment circuits)** → ~3–4  
Rationale: strong preclinical in vivo feasibility and concrete containment strategies, but limited evidence of routine, regulated real-world deployment at scale. [62]

**Aggregation method:** average-based (bundle with materially different application contexts). Averaging the above (6, 4, 6, 5, ~3.5) yields ~4.9 → rounded to **5**, reflecting that while some applications are already “product-level”, the ART’s defining bottleneck—**repeatable design + control across ecosystems**—is not yet at the deployment-and-scaling stage required for a 6–7 overall score. ## ART 09.073 Precision Medicine & Genomic Diagnostics

### ART extraction

#### A) Primary capability claimed (core output of the ART)

- Combine low-cost whole-genome (or near-whole-genome) sequencing with repeatable, minimally invasive molecular sampling (e.g., blood-based multi-omics) to produce *actionable* risk estimates, treatment response predictions, and longitudinal monitoring markers. [\[1\]](#)
- Deliver results as plain-language summaries with confidence and follow-up recommendations (rather than raw genomic data), and expose standardised software interfaces so authorised tools can query results and trigger clinical decision support. [\[2\]](#)
- Operate as an evolving “learning” system: continuously updated reference datasets and models, plus audit trails tying recommendations to supporting evidence. [\[3\]](#)

#### B) Key sub-components / sub-threads in the bundle (technology + deployment stack)

- Clinical-grade whole-genome sequencing (short-read WGS as current workhorse, plus increasing long-read WGS to resolve complex genes/structural variants). [\[4\]](#)
- Variant interpretation infrastructure (curated knowledgebases and classification processes; ongoing updating and re-interpretation workflows). [\[5\]](#)
- Interoperability layer (standardised APIs and data models linking genomics repositories to EHR/workflow apps). [\[6\]](#)
- Longitudinal molecular monitoring (cfDNA methylation-based multicancer early detection; blood-based multi-omics predictors of therapy response; proteomic risk prediction models). [\[7\]](#)
- Population-scale reference datasets with improved diversity representation (required for generalisable risk estimation). [\[8\]](#)
- Operational governance in real health systems (test directories/commissioning, turnaround-time monitoring, national data flows) and associated privacy/consent controls. [\[9\]](#)

#### C) What maturity indicators would count as evidence for this ART

- National or population-scale deployments producing and using genomic data at high volume (clear indicator of scale, pipeline stability, and investment). [\[10\]](#)
- Clinical commissioning / routine service integration (e.g., a national test directory specifying which genomic tests are paid for, and by whom). [\[11\]](#)
- Demonstrated clinical feasibility and quantified false-positive/false-negative burden for longitudinal monitoring (especially screening/early detection). [\[12\]](#)
- Peer-reviewed evidence that new modalities improve actionable performance vs prior baselines (e.g., diagnostic yield uplift from long-read sequencing; improved prediction from proteomics). [\[13\]](#)
- Standardised data exchange mechanisms (published interfaces/operations; evidence of pilots/ballots) enabling cross-organisation tooling. [\[6\]](#)

- Evidence maintenance/updates in interpretation knowledgebases (a practical requirement for continuous learning and auditability). [5]

## 2. Evidence (10–20 recent, reliable sources)

**Source selection note:** All entries below are within the strict window **Feb 2022–Feb 2026** and prioritise peer-reviewed papers plus authoritative public programmes and standards artefacts.

### 1) Recommendations for whole genome sequencing in diagnostics for rare diseases

**Authors/organisation:** EuroGentest[14] and the Solve-RD[15] initiative (multi-author guidance)

**Venue/type:** Peer-reviewed guideline article (European Journal of Human Genetics)

**Publication date:** May 2022 (version of record; issue date Sept 2022)

**Link:** <https://www.nature.com/articles/s41431-022-01113-x>

**Why it matters:** Explicitly frames WGS as increasingly introduced for rare disease diagnostics and motivates updated guidance because WGS can capture multiple variant classes (including structural variants and repeat expansions), directly supporting plausibility and clinical integration signals. [16]

### 2) Recommendations for reporting results of diagnostic genomic testing

**Authors/organisation:** European Society of Human Genetics[17]-led expert group (multi-author consensus)

**Venue/type:** Peer-reviewed guideline article (European Journal of Human Genetics)

**Publication date:** April 2022 (published online)

**Link:** <https://doi.org/10.1038/s41431-022-01091-0>

**Why it matters:** Provides concrete reporting guidance intended to reduce misinterpretation and explicitly recognises modern result types (including CNVs and mentions of polygenic risk scores/pharmacogenetics), aligning with the ART’s “plain-language summary + careful communication” requirement. [18]

### 3) National genomic test directory: Testing criteria for rare and inherited disease (Eligibility criteria), Version 7

**Authors/organisation:** NHS England[19]

**Venue/type:** National commissioning criteria (authoritative health-system document)

**Publication date:** July 2024

**Link:** <https://www.england.nhs.uk/wp-content/uploads/2024/07/national-genomic-test-directory-rare-and-inherited-disease-eligibility-criteria-v7.pdf>

**Why it matters:** Demonstrates “real system” maturity: the document states the National Genomic Test Directory governs which tests are commissioned and paid for by the NHS and must be delivered by Genomic Laboratory Hubs—strong evidence of operational integration beyond research pilots. [11]

### 4) England Rare Diseases Action Plan 2024: main report

**Authors/organisation:** UK Government (Department of Health and Social Care)

**Venue/type:** Government programme report / roadmap

**Publication date:** 2024

**Link:** <https://www.gov.uk/government/publications/england-rare-diseases-action-plan-2024/england-rare-diseases-action-plan-2024-main-report>

**Why it matters:** States that transfer of whole-genome sequencing data to the national congenital anomaly and rare disease registration service was expected in early 2024 and intended to expand after initial proof-of-principle, indicating scaling of genomic data flows and governance—not just sequencing capacity. [20]

#### 5) NHS Genomic Medicine Service data release v1 (15/06/2022)

**Authors/organisation:** Genomics England[21]

**Venue/type:** Programme data release note (authoritative consortium technical documentation)

**Publication date:** June 2022

**Link:** [https://re-docs.genomicsengland.co.uk/gms\\_release1/](https://re-docs.genomicsengland.co.uk/gms_release1/)

**Why it matters:** A dated “data release” indicates durable operational infrastructure (data models, release processes, and controlled access) consistent with an ecosystem where genomic outputs “travel across organisations over time.” [22]

#### 6) NHS Genomic Medicine Service data release v5 (28/08/2025)

**Authors/organisation:** Genomics England

**Venue/type:** Programme data release note (authoritative consortium technical documentation)

**Publication date:** August 2025

**Link:** [https://re-docs.genomicsengland.co.uk/gms\\_release5/](https://re-docs.genomicsengland.co.uk/gms_release5/)

**Why it matters:** Later release numbering and dated publishing show the programme is iterating continuously (release cadence + change summaries), supporting maturity as an evolving “learning” data platform rather than a one-off project. [23]

#### 7) DNA Sequencing Costs: Data

**Authors/organisation:** National Human Genome Research Institute[24]

**Venue/type:** Authoritative government cost-tracking dataset and methodology note
